Yvette Kosmann-Schwarzbach

Groups and Symmetries

From Finite Groups to Lie Groups

Translated by Stephanie Frank Singer

Springer
Sophus Lie (1842–1899), around 1865, at the end of his studies at the University of Christiana (Oslo), approximately seven years before his first work on continuous groups, later known as “Lie groups.”

Johnny walked to a corner of the room, faced the wall, and started mumbling to himself. After a while he turned around and said: “You need the theory of group characters.” Whereupon von Neumann went to Issai Schur, obtained reprints of two of his papers and gave them to Wigner.¹

Symmetries of geometric figures, crystals, and other macroscopic physical items have been observed and analyzed for centuries. In modern terms, the symmetries of an object form a group. The idea of a group emerged slowly in the middle of the nineteenth century. Afterward, though, the study of groups accelerated markedly. Due to the work of Sophus Lie (1842–1899), Georg Frobenius (1849–1917), Wilhelm Killing (1847–1923), Élie Cartan (1869–1951), Issai Schur (1875–1941), Hermann Weyl (1885–1955), and many, many others, group theory expanded enormously. Applications to quantum mechanics and elementary particle theory were developed throughout the twentieth century. If this history interests you, read the introduction to Group Theory and Physics by Shlomo Sternberg (1994), and consult the books by Charles Curtis (1999), Thomas Hawkins (2000), and Armand Borel (2001), or the essays and transcriptions of round tables between physicists and mathematicians in the volume Symmetries in Physics.²

Sophus Lie wrote in an 1877 letter to the mathematician Adolph Mayer³ that he had “created group theory” in January 1873. He was certainly referring to the groups that he called “continuous” and that have since become known

³ Mayer (1839–1908) was a professor at the University of Heidelberg whose work on the calculus of variations and partial differential equations was close to that of Lie.
as “Lie groups” and in French as “groupes de Lie.”\textsuperscript{4} Lie was trying to extend the application of groups from the study of algebraic equations, where Évariste Galois had introduced them, to the study of differential equations. Inspired by the work of Camille Jordan and by a collaboration with Felix Klein, Lie published an article titled \textit{"Uber Gruppen von Transformationen} in 1874. As early as 1871, the idea of an infinitesimal generator of a one-parameter group of transformations had already appeared in his work;\textsuperscript{5} the set of infinitesimal generators of one-parameter subgroups of a continuous group forms what today is called a “Lie algebra.”\textsuperscript{6} Between 1888 and 1890, Killing established a classification of semisimple Lie algebras over the field of complex numbers, which was corrected and completed by Cartan in his 1894 thesis. Cartan would succeed in classifying Lie algebras over the field of real numbers, a more difficult problem, in 1914.

Frobenius, in response to a question that had been posed by Dirichlet,\textsuperscript{7} invented the theory of characters of finite groups in 1896, and Schur, beginning in 1901, developed the representation theory of finite and infinite groups. Their joint work, \textit{"Uber die reellen Darstellungen der endlichen Gruppen}, was published in the proceedings of the Berlin Academy in 1906. The theory of characters was used by William Burnside in the second edition of his treatise \textit{Theory of Groups of Finite Order}, which appeared in 1911.

It was Eugene Wigner and Weyl who showed the pertinence of group theory, particularly group representations, for the quantum mechanics being developed in the 1920s by Werner Heisenberg and Paul Dirac. Wigner was the first to introduce group theory into physics in two articles in the \textit{Zeitschrift f"ur Physik} in 1927. His book \textit{Gruppentheorie und ihre Anwendung auf die Quantenmechanik der Atompektren}, which appeared in 1931, was followed in 1939 by a fundamental article in the \textit{Annals of Mathematics} in which he determined the representations of the Poincaré group. At the end of 1927, Weyl published an article in the \textit{Zeitschrift f"ur Physik} in which he introduced what is now called “Weyl quantization,” and the first edition of his \textit{Gruppentheorie und Quantenmechanik} came out in 1928. In 1932 Bartel van der Waerden’s \textit{Die gruppentheoretische Methode in der Quantenmechanik} appeared. These three books marked the beginning of the use of group theory in theoretical physics, which continues to this day.

After Heisenberg had solved a two-electron problem related to the spectrum of the helium atom, Wigner became interested in the more-than-two-identical-particles problem. He first solved the case of three elements, then went

\textsuperscript{4} The term “groupes de Lie” first appeared in French in 1893 in the thesis of Lie’s student Arthur Tresse. See p. 46.
\textsuperscript{5} This point of view was essential to Emmy Noether’s 1918 article in the \textit{G"ottinger Nachrichten} establishing the relationship between symmetries of a variational problem and conservation laws. About ten years later, Noether published a very important article situating the representation theory of finite groups and of algebras in the context of noncommutative rings.
\textsuperscript{6} This name was suggested much later by Weyl in his 1933–1934 lectures at the Institute for Advanced Study in Princeton.
\textsuperscript{7} Peter Gustav Lejeune Dirichlet (1805–1859) taught in Paris, Breslau (now Wroclaw), Berlin, and finally G"ottingen. His works on number theory and on analysis are equally fundamental.
to consult von Neumann on how to extend his already very complicated computations to the case of an arbitrary number of electrons. In 1983, he recalled, 8

As to representation theory: I realized that there must be such a theory but I had no knowledge of it. Dr. von Neumann to whom I presented the problem (and I presented to him the representations of the permutation groups of three and four elements because those I could establish by long hand calculations) gave me a reprint of the article of Frobenius and Schur [1906]. And that was wonderful!

One may consider group representation theory as a vast generalization of Fourier analysis. It has been developed continuously and has, since the middle of the twentieth century, seen innumerable applications to differential geometry, ergodic theory, probability theory, number theory, the theory of automorphic forms, and dynamical systems, as well as to physics, chemistry, molecular biology, and signal processing. Currently it is the basis of several branches of mathematics and physics.

***

The aim of this course is to introduce and illustrate the basic notions of finite group theory and, more generally, compact topological groups, to introduce the notions of Lie algebras and Lie groups, at least in the case of linear Lie groups (closed subgroups of the linear groups), to study the Lie groups SO(3) and SU(2) in detail, and then the Lie group SU(3) and its application to the theory of quarks. The idea of a group representation, an action on a vector space by linear transformations, plays the most fundamental role in this study.

In Chapter 1, we recall some general facts about groups and group actions, and we give examples of finite and infinite groups.

To study the representations of finite groups, we exploit the properties of the characters of these representations, that is, the traces of the linear transformations that define the representation in question. This is done in Chapter 2, where we define irreducible representations and intertwining operators. We state Schur’s lemma which, though simple, will be essential to the proofs of important consequences such as the orthogonality of the characters of irreducible representations. We study the regular representation. A brief paragraph will introduce induced representations.

Chapter 3 extends certain results proved for finite groups to compact groups, using the existence of an invariant measure on each compact group, the Haar measure. In this chapter, some topological and analytic results are stated without proof and references to the literature are supplied. A table summarizes the properties of representations of compact groups.

The beginning of Chapter 4 consists of an introduction to the general notion of a Lie algebra and a review of exponentiation of matrices. Next we study the Lie algebra of a linear Lie group, that is, the set of infinitesimal generators of one-parameter subgroups, with the operation of matrix commutation, and we show the relationship between the representations of a Lie group and the representations of its Lie algebra.

8 Round Table on the Evolution of Symmetries, chaired by Louis Michel, in Doncel et al., p. 633.
In Chapter 5 we study the Lie groups SO(3) and SU(2), proving the fundamental property that SU(2) is the universal cover of the rotation group. In Chapter 6 we determine all the irreducible representations, first of $\mathfrak{sl}(2, \mathbb{C})$, and then of SU(2) and SO(3). These results are as important for the general theory of group representations as they are for quantum mechanics.

Chapter 7 consists of a study of spherical harmonics, which appear in the representation theory of the group of rotations of Euclidean space of three dimensions. This is an introduction to the theory of special functions.

In Chapter 8 we begin the study of irreducible representations of SU(3) by considering examples, and we show that quark theory appears as a consequence of the mathematical properties of this group. In this chapter we introduce the roots and weights that are, more generally, the essential tools the representation theory of a large class of Lie algebras, the semisimple Lie algebras.

We have introduced much notation and many concepts used in physics in the hope that this book will be useful to students in the physical sciences as well as in mathematics. Except for Chapters 3 and 8, complete proofs of all results are given. The symbol □ denotes the end of a proof. At the end of each chapter we give bibliographic references to the principal sources of the material treated in the chapter and references for further study. For each chapter, there are exercises of various degrees of difficulty, many of which introduce additional definitions and results. The eight chapters are followed by a series of nine problems with detailed solutions, which constitute both an application of results proved in this book and an introduction to several more advanced topics. The book ends with a bibliography and an index.

This textbook arose from a course taught for several years at the École Polytechnique to third-year students majoring in mathematics or physics. This course, roughly corresponding to an advanced undergraduate or beginning graduate course, was taught in nine weeks as ninety-minute lectures followed by two-hour exercise sessions. The problems that complement the text are drawn from the examinations that were administered at the end of the term.

This book is designed to serve as an introduction to more advanced texts and to encourage the reader to develop and use the ideas sketched here. The bibliography at the end of this work contains some very classical texts, several books on the history of the subject, recent textbooks on diverse aspects of group and representation theory, books that will be useful as reference for results not proved here, and books that further develop harmonic analysis or representation theory in various ways, chosen from an extremely vast literature. Among these works, we have starred those that are most directly related to the matter treated in this text. Others, perhaps in spite of their titles, go “beyond an introduction.” We hope that our readers will find instruction and pleasure in this book.

Paris, July 2009
Acknowledgments

This English edition is a revised and adapted version of *Groupes et Symétries: Groupes finis, groupes et algèbres de Lie, représentations*, Éditions de l’École Polytechnique, 2006, itself a revised edition of the first edition (2004). I am very grateful to the translator, Dr. Stephanie Singer, for her excellent translation, to Ann Kostant and the editors of the series *Universitext* for accepting this short textbook for publication, and to the staff of Springer, New York, for their help in its preparation. I also thank the institutions and colleagues who kindly allowed me to reproduce the portraits of mathematicians and physicists that illustrate this book.

I wish to reiterate my thanks to all those who helped me in the preparation of the French editions: Alain Guichardet, for his numerous comments on the notes that preceded this book, André Rougé for his clarification of the history of the eightfold way, my colleagues Nicole Berline and Pascale Harinck, as well as Jean-Paul Blaizot and Jean-Claude Tolédano, for their encouragement and useful feedback, and the students of the École Polytechnique from whose remarks I have learned a great deal. I am grateful to Shlomo Sternberg, whose book on group theory and physics inspired me greatly, and to Adrian Ocneanu, of Pennsylvania State University, who sent me diagrams illustrating the theory of roots of Lie algebras, one of which appears on the cover of *Groupes et Symétries.*
Wilhelm Killing (1847–1923) around 1890, shortly after the publication of his innovative work on the properties of infinitesimal isometries of “space forms,” generalizations of Euclidean space. This study brought him to the idea that much later was called “Lie algebra.” Eventually he classified semisimple Lie algebras.

(Portrait collection, Universitäts- und Landesbibliothek Münster)
Chapter 1

General Facts About Groups

1 Review of Definitions

A group is a set equipped with an associative composition law, containing an identity element and such that each element has an inverse. The identity element, also called the unit element, may be denoted by $e$, 1, or, in the case of a matrix group, $I$.

A group is called commutative or abelian if its composition law is commutative. In this case the composition is generally denoted by $+$ and the identity element is generally denoted by 0.

We denote by $|X|$ the cardinality of a finite set $X$. The order of a finite group $G$ is the number $|G|$ of elements of the group.

An element $g \in G$ is said to be of order $n$ ($n \geq 1$) if $n$ is the smallest integer such that $g^n = e$.

Example. The rotation through an angle $2\pi/n$ is an element of order $n$ in the group of rotations of the plane.

A subgroup $H$ of $G$ is a subset satisfying the conditions $e \in H$, $g \in H$ implies $g^{-1} \in H$, if $g \in H$ and $g' \in H$ then $gg' \in H$.

The subgroup generated by a subset of a group $G$ is the smallest subgroup of $G$ containing the subset.

A group is called cyclic if it is generated by a single element. Such a group is abelian.

Let $H$ be a subgroup of $G$. The left $H$-cosets are the sets $gH$, $g \in G$. The set of left $H$-cosets is the quotient set $G/H$. The right $H$-cosets are the sets $Hg$, $g \in G$. The set of right $H$-cosets is the quotient set $H \backslash G$. The set $G$ is the union of left (respectively, right) $H$-cosets, each of which has $|H|$ elements. We deduce that the order of $H$ divides the order of $G$, and that the number of left $H$-cosets equals the number of right $H$-cosets. We can now state the following result.

Theorem 1.1 (Lagrange’s Theorem). Let $G$ be a finite group and let $H$ be a subgroup of $G$. Then $|H|$ divides $|G|$ and

$$|G|/|H| = |H \backslash G| = |G/H|.$$

The integer $|G|/|H|$ is called the index of $H$ in $G$. 
A morphism of groups (or group morphism) \( \varphi : G_1 \rightarrow G_2 \) is a mapping of a group \( G_1 \) into a group \( G_2 \) such that for every \( g, g' \in G_1 \), \( \varphi(gg') = \varphi(g)\varphi(g') \), which implies that \( \varphi(e_1) = e_2 \), where \( e_i \) is the identity element of \( G_i \) (\( i = 1, 2 \)), and \( \varphi(g^{-1}) = (\varphi(g))^{-1} \). Note that most authors use the term homomorphism.

An isomorphism of groups is a bijection that is also a morphism. Its inverse is then also a morphism.

An automorphism of a group is an isomorphism of a group onto itself. In particular, for each \( g \in G \), the isomorphism \( C_g \) of \( G \) defined by \( C_g : h \mapsto ghg^{-1} \) is called an inner automorphism or a conjugation.

A subgroup of \( G \) is called normal or invariant if it is stable under conjugation by every element of \( G \).

If a subgroup \( H \) of \( G \) is normal, then for each \( g \in G \), \( gH = Hg \), and the set of what we may now call the set of \( H \)-cosets is then a group, called the quotient group of \( G \) by \( H \), and denoted by \( G/H \). The projection \( p : G \rightarrow G/H \), defined by \( g \mapsto gH \), is a morphism of groups.

The kernel of a morphism of groups \( \varphi : G_1 \rightarrow G_2 \) is a normal subgroup of \( G_1 \). Conversely, if \( H \) is a normal subgroup of a group \( G \), then it is the kernel of a group morphism, the projection \( p : G \rightarrow G/H \).

The center of \( G \) is by definition the set \( \{ h \in G \mid \forall g \in G, gh = hg \} \). The center of \( G \) is a normal subgroup of \( G \).

If \( G_1 \) and \( G_2 \) are groups, their direct product is the product \( G_1 \times G_2 \) with group law \((g_1, g_2)(g_1', g_2') = (g_1g_1', g_2g_2')\).

The notion of a semidirect product of groups is introduced in Exercise 1.4.

2 Examples of Finite Groups

2.1 Cyclic Group of Order \( n \)

For \( n \) a positive integer, the set of integer multiples of \( n \) is denoted by \( n\mathbb{Z} \). It is a subgroup of the abelian group \( \mathbb{Z} \); in fact, it is a normal subgroup, since all subgroups of an abelian group are normal.

The following groups are isomorphic and are called cyclic groups of order \( n \):

- \( \mathbb{Z}_n = \mathbb{Z}/n\mathbb{Z} \), in particular \( \mathbb{Z}_2 = \mathbb{Z}/2\mathbb{Z} \), denoted additively by \( \{0, 1\} \) or multiplicatively by \( \{1, -1\} \).
- The group of rotations of the plane around the origin through angles \( 2k\pi/n, 0 \leq k \leq n - 1 \), under composition.
- The group of complex numbers \( \{e^{2ik\pi/n} \mid 0 \leq k \leq n - 1\} \) under multiplication.
- The subgroup \( \{1, g, g^2, \ldots, g^{n-1}\} \) if \( g \) is an element of order \( n \) in a group \( G \).

A cyclic group is generated by a single element.
2.2 Symmetric Group $\mathfrak{S}_n$

The permutation group of a set of cardinality $n$ is denoted by $\mathfrak{S}_n$ and called the symmetric group on $n$ elements. The order of $\mathfrak{S}_n$ is $n!$.

Every element of $\mathfrak{S}_n$ can be written as a product of transpositions. To every element $\sigma \in \mathfrak{S}_n$, we associate the number 1 or $-1$ according to the parity of the number of transpositions, which parity is independent of the decomposition. This number is denoted by $(-1)^\sigma$ and called the signature of $\sigma$. The map $\sigma \in \mathfrak{S}_n \mapsto (-1)^\sigma \in \mathbb{Z}_2$ is a group morphism, called the signature morphism.

The alternate group $\mathfrak{A}_n$ is the kernel of the signature morphism. If $n \geq 2$, it is a normal subgroup of index 2 of $\mathfrak{S}_n$.

2.3 Dihedral Group

The dihedral group $D_{(n)}$ is the group of rotations and symmetries of the plane preserving a regular $n$-sided polygon ($n \geq 3$). It is a subgroup of $\mathfrak{S}_n$ of order $2n$. Some authors use the notation $D_{2n}$ for this group. (See Exercise 1.6.)

2.4 Other Examples

We denote by $O(3)$ the group of linear isometries of $\mathbb{R}^3$, and by $SO(3)$ the group of rotations of $\mathbb{R}^3$, which is the kernel of the determinant map on $O(3)$, and thus a normal subgroup of $O(3)$. For each regular polyhedron—tetrahedron, cube, octahedron, icosahedron (fullerene), dodecahedron—we define the corresponding groups of symmetries, that is, the subgroup of $SO(3)$ and the subgroup of $O(3)$ leaving the solid globally invariant. These are finite groups, and they are known as crystallographic groups. The first is of index 2 in the second:

The classification of all finite subgroups of $SO(3)$ and of $O(3)$, which is well known, is of great importance in physics, in particular in crystallography.

3 Examples of Infinite Groups

Among the groups with an infinite number of elements, there are discrete groups such as, for example, the abelian group $\mathbb{Z}$. But we are mainly interested in the nondiscrete groups called “continuous groups,” of which we now give examples.

Let $\mathbb{K}$ denote the field $\mathbb{R}$ or $\mathbb{C}$. We denote by $GL(n, \mathbb{K})$ the group of linear isomorphisms of $\mathbb{K}^n$, called the linear group of dimension $n$. This is the group of invertible $n \times n$ matrices with coefficients in $\mathbb{K}$, of which we shall consider several subgroups. We denote the transpose of a matrix $A$ by $^tA$. The complex conjugate of a complex number or matrix is denoted by a bar over that number or matrix.
• Special linear group over $\mathbb{K}$:
  \[
  \text{SL}(n, \mathbb{K}) = \{ A \in \text{GL}(n, \mathbb{K}) \mid \det A = 1 \}.
  \]

• Orthogonal group over $\mathbb{K}$:
  \[
  \text{O}(n, \mathbb{K}) = \{ A \in \text{GL}(n, \mathbb{K}) \mid A^tA = I \}.
  \]

  In particular, we call the real orthogonal group the \textit{orthogonal group} and we denote it simply by $\text{O}(n)$.

• Special orthogonal group over $\mathbb{K}$:
  \[
  \text{SO}(n, \mathbb{K}) = \{ A \in \text{O}(n, \mathbb{K}) \mid \det A = 1 \}.
  \]

  In particular, we call the real special orthogonal group the \textit{special orthogonal group}, and we denote it simply by $\text{SO}(n)$.

More generally, if $p + q = n$, we denote by $J_{pq}$ the diagonal matrix with $p$ diagonal elements 1 followed by $q$ diagonal elements $-1$, and we set

\[
\text{O}(p, q) = \{ A \in \text{GL}(n, \mathbb{R}) \mid A J_{pq} A^t = J_{pq} \}
\]

and

\[
\text{SO}(p, q) = \{ A \in \text{O}(p, q) \mid \det A = 1 \}.
\]

In particular, $\text{O}(3, 1)$, the group of isometries of Minkowski space, is called the \textit{Lorentz group}.

• Unitary group:
  \[
  \text{U}(n) = \{ A \in \text{GL}(n, \mathbb{C}) \mid A^* A = I \}.
  \]

  The matrix $^*A$ is the adjoint of the matrix $A$, also denoted by $A^*$.

• Special unitary group:
  \[
  \text{SU}(n) = \{ A \in \text{U}(n) \mid \det A = 1 \}.
  \]

\textbf{Definition 3.1.} A topological group is a group $G$ that is a Hausdorff topological space such that multiplication $(g, g') \mapsto gg'$ is a continuous map of $G \times G$ into $G$ and inversion $g \mapsto g^{-1}$ is a continuous map of $G$ into $G$.

The linear group $\text{GL}(n, \mathbb{K})$ with its usual topology (as an open subset of $\mathbb{K}^{n^2}$) is a locally compact topological group, and each of the groups listed above is a closed subgroup of a linear group. The groups $\text{O}(n)$ and $\text{U}(n)$, as well as $\text{SO}(n)$ and $\text{SU}(n)$, are compact.

Below we give the definition of real and complex Lie groups, which brings in the notion of \textit{manifolds}, an abstraction of the notion of a surface in Cartesian space.

A \textit{(real) Lie group} of (real) dimension $N$ is a group that is a smooth (real) manifold of dimension $N$ such that multiplication and inversion are smooth differentiable maps.
A complex Lie group of complex dimension $N$ is a group that is a complex-analytic manifold of complex dimension $N$ such that multiplication and inversion are analytic maps.

All closed subgroups of $\text{GL}(n, \mathbb{K})$ are real Lie groups, called linear Lie groups. This is a theorem that we state without proof. The linear Lie groups are the only ones we consider, and we shall call them simply Lie groups. Thus all of the examples above are examples of Lie groups. There are other examples of Lie groups: the symplectic groups $\text{Sp}(n)$ and $\text{Sp}(n, \mathbb{C})$, the spinor groups, etc. In this text we study the Lie groups $\text{SO}(3)$ and $\text{SU}(2)$ in detail.

**Remark.** Every complex Lie group of complex dimension $N$ is a real Lie group of real dimension $2N$. The group $\text{GL}(n, \mathbb{C})$ and some of its subgroups are also complex Lie groups. This is the case for $\text{SL}(n, \mathbb{C})$, $\text{O}(n, \mathbb{C})$, and $\text{SO}(n, \mathbb{C})$ but, not for $\text{U}(n)$, nor for $\text{SU}(n)$, which are real Lie groups only.

### 4 Group Actions and Conjugacy Classes

**Definition 4.1.** Let $G$ be a group and let $M$ be a set. A group action (or simply an action) of $G$ on $M$ is a mapping $\alpha : G \times M \rightarrow M$, denoted by $(g, m) \mapsto g \cdot m$, such that for every $m \in M$, $e \cdot m = m$, and for every $g$ and $g' \in G$, $g \cdot (g' \cdot m) = (gg') \cdot m$. In this case we say that $G$ acts on $M$.

In other words, $\alpha$ defines a group morphism of $G$ into the group of bijections of $M$ onto itself.

If $G$ is a topological group and if $M$ is a topological space, we shall assume that the action $\alpha$ of $G$ on $M$ is continuous. If $G$ is a Lie group and if $M$ is a smooth manifold, we shall similarly assume that $\alpha$ is smooth.

The orbit of $m \in M$ under the action of $G$ is the set $\{g \cdot m \mid g \in G\}$. The orbits define a partition of $M$.

**Examples.**

- The trivial action of $G$ on a set $M$ consists in sending each element of the group to the identity mapping of $M$ onto itself. In this case, the orbits are the points of $M$.
- Under the action of $G = \text{O}(2)$ on the unit sphere $M = S^2 \subset \mathbb{R}^3$ by rotations around the axis $Oz$, the orbit of $m \in S^2$ is a point if $m$ is the north pole or the south pole, and is otherwise a circle around the axis $Oz$ (a one-dimensional submanifold).
- The action of $G$ on $G$ by left (respectively, right) translation is the action
  \[(g, m) \in G \times G \mapsto gm \in G\]
  (respectively, $(g, m) \in G \times G \mapsto mg^{-1} \in G$). In other words, we associate to $g \in G$ the left (respectively, right) translation $l_g$ (respectively, $r_{g^{-1}}$) in $G$, thus defining a morphism of $G$ into the bijections of $G$ onto $G$ (but not into the automorphisms of $G$).

We remark that the left coset $gH$ of $g \in G$ relative to a subgroup $H$ of $G$ is the orbit of $g$ under the action of $H \subset G$ acting by right translation.
The action of $G$ on $G$ by conjugation, denoted by $(g,h) \mapsto C_g(h)$ and defined by
\[ C_g(h) = ghg^{-1}, \]
is an action of $G$ on itself by automorphisms. The orbit of $h \in G$,
\[ C_h = \{ghg^{-1} \mid g \in G\}, \]
is called the *conjugacy class* of $h$.

**Examples.**

- The conjugacy class of $e$ is $\{e\}$.
- If $G$ is abelian, the conjugacy class of $g \in G$ is $\{g\}$. This is the case, for example, for $SO(2)$.
- In $\mathfrak{S}_n$, the number of conjugacy classes is the number of *partitions* of $n$. (See Exercise 1.3.)
- In $\text{GL}(n, \mathbb{K})$, the conjugacy class of a matrix $A$ is the set of all matrices similar to $A$, $\{PAP^{-1} \mid P \in \text{GL}(n, \mathbb{K})\}$.
- In $SO(3)$, two rotations are conjugate by a rotation if and only if their angles are equal or opposite. The conjugacy classes are in bijective correspondence with the interval $[0, \pi]$.

In fact, by a direct orthonormal change of basis, any rotation can be written as $g(\theta) = \begin{pmatrix} 1 & 0 & 0 \\ 0 & \cos \theta & -\sin \theta \\ 0 & \sin \theta & \cos \theta \end{pmatrix}$, with $\theta \in [0, 2\pi]$. From the equality $g(-\theta) = g_0g(\theta)g_0^{-1}$, where $g_0 = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{pmatrix}$, it is easy to see that $g(\theta')$ is conjugate to $g(\theta)$ if and only if $\theta' = \theta$ or $\theta' = -\theta$.

**References**

For the classification of the finite subgroups of $SO(3)$, see Sternberg (1994), Artin (1991), or Ledermann–Weir (1996). Sternberg also analyzes the subgroups of $O(3)$ and identifies, for each subgroup, a crystal possessing that symmetry.

Basic notions in topology such as discrete spaces, Hausdorff spaces, compact and locally compact spaces, as well as connected spaces, are recalled in many books on representation theory. See, e.g., Stillwell (2008) or Naimark–Stern (1982).

One can find an introduction to the theory of differentiable manifolds and Lie groups in Sagle–Walde (1973) and Rossmann (2002), and, with applications to mechanics, in Marsden–Ratiu (1999). For the study of the differential geometry of Lie groups considered as manifolds see, for example, Warner (1983).

**Exercises**

**Exercise 1.1 Application of Lagrange’s Theorem.**

Show that in a finite group $G$ of order $n$, for each element $a \in G$, $a^n = e$. Conclude that every morphism of $G$ into the group $\text{GL}(1, \mathbb{C}) = \mathbb{C}^*$ takes values in the group of $n$th roots of unity.
Exercise 1.2 Center of $\mathfrak{S}_n$.
Show that for $n \geq 3$, the only element in the center of the symmetric group $\mathfrak{S}_n$ is the identity.

Exercise 1.3 Conjugacy classes of $\mathfrak{S}_n$.
An element in $\mathfrak{S}_n$ is called a cycle of length $k$ $(1 \leq k \leq n)$ if it is a circular permutation of $k$ elements that leaves the other $n-k$ elements invariant.

(a) Show that each permutation is the composition of disjoint cycles. Is this decomposition unique?
(b) Show that in $\mathfrak{S}_n$ two elements are conjugate if and only if they have the same decomposition into cycles. Deduce that the number of conjugacy classes of $\mathfrak{S}_n$ is the number of partitions of the integer $n$, that is, of finite sequences of integers $\lambda_1, \lambda_2, \ldots, \lambda_\ell$ such that $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_\ell > 0$, and $\sum_{i=1}^\ell \lambda_i = n$.

Exercise 1.4 Semidirect products of groups.
If a group $H$ acts on a group $N$ by group automorphisms, we define a multiplication on $G = N \times H$ by

$$(n, h)(n', h') = (n(h \cdot n'), hh').$$

(a) Show that, equipped with this multiplication, $G$ is a group. This group, denoted by $N \rtimes H$, is called the semidirect product of $N$ and $H$. What is the inverse of $(n, h)$ in $G$? Show that $N$ is a normal subgroup of $G$.
(b) Show that the group $\mathfrak{S}_3$ is the semidirect product of the alternate group $\mathfrak{A}_3$ and $\mathbb{Z}_2$. Is the group $\mathfrak{S}_n$ a semidirect product of the alternate group $\mathfrak{A}_n$ and $\mathbb{Z}_2$, for $n \geq 3$?
(c) Find the standard definitions of the Galilean group and the Poincaré group in any textbook. Show that each of these groups is a semidirect product.

Exercise 1.5 Group of isometries of the plane.

(a) Show that the group $\mathbb{Z}_2 = \{1, -1\}$ acts by group automorphisms on $\text{SO}(2)$ via $\varepsilon \cdot g = g^\varepsilon$, where $\varepsilon = \pm 1$. Show that $\text{O}(2)$ is the semidirect product $\text{SO}(2) \rtimes \mathbb{Z}_2$.
(b) Determine the conjugacy classes of $\text{SO}(2)$ and of $\text{O}(2)$.

Exercise 1.6 The dihedral group $D_{(n)}$.
Let $D_{(n)}$ be the dihedral group of order $2n$, i.e., the group of rotations and symmetries of the plane that leave invariant a regular $n$-sided polygon $(n \geq 3)$.

(a) Show that $D_{(n)} = \Gamma_n \rtimes \mathbb{Z}_2$, where $\Gamma_n$ is the cyclic group of order $n$ and the group $\mathbb{Z}_2 = \{1, -1\}$ acts on $\Gamma_n$ by $\varepsilon \cdot g = g^\varepsilon$, where $\varepsilon = \pm 1$.
(b) Show that $D_{(n)}$ is isomorphic to $\mathfrak{S}_n$ if and only if $n = 3$.
(c) The set $\{\pm 1, \pm i, \pm j, \pm k\}$, with multiplication law $i^2 = j^2 = k^2 = -1$, $ij = -ji = k$, $jk = -kj = i$, $ki = -ik = j$, is a group, called the quaternion group. Show that $D_{(4)}$ is not isomorphic to the quaternion group.
Ferdinand Georg Frobenius (1849–1917), who created the representation theory of finite groups around 1896, was a professor in Berlin and Zurich.

Chapter 2

Representations of Finite Groups

In mathematics and physics, the notion of a group representation is fundamental. The idea is to study the different ways that groups can act on vector spaces by linear transformations.

In this chapter, unless otherwise indicated, we shall consider only representations of finite groups in complex, finite-dimensional vector spaces.

1 Representations

1.1 General Facts

Let $G$ be a finite group. If $E$ is a vector space over $\mathbb{K}$, where $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$, we denote by $\text{GL}(E)$ the group of $\mathbb{K}$-linear isomorphisms of $E$. (The group $\text{GL}(E)$ is not finite unless $E = \{0\}$.)

Definition 1.1. A representation of a group $G$ is a finite-dimensional complex vector space $E$ along with a group morphism of groups $\rho : G \to \text{GL}(E)$.

Thus, for every $g, g' \in G$,

$$\rho(gg') = \rho(g)\rho(g'), \quad \rho(g^{-1}) = (\rho(g))^{-1}, \quad \rho(e) = \text{Id}_E.$$

The vector space $E$ is called the support of the representation, and the dimension of $E$ is called the dimension of the representation. We denote such a representation by $(E, \rho)$ or simply $\rho$.

If in particular $E = \mathbb{C}^n$, we say that the representation is a matrix representation of dimension $n$.

The fundamental representation of a subgroup $G$ of $\text{GL}(E)$ is the representation of $G$ on $E$ defined by the canonical injection of $G$ into $\text{GL}(E)$.

Any representation such that $\rho(g) = \text{Id}_E$ for each $g \in G$ is called a trivial representation.
Example 1.2. Here is a first example of a representation of a nonabelian group. Let \( t \in S_3 \) be the transposition \( 123 \mapsto 132 \) and \( c \) the cyclic permutation \( 123 \mapsto 231 \) that generate \( S_3 \). We set \( j = e^{2i\pi/3} \), so that \( j^2 + j + 1 = 0 \). We can represent \( S_3 \) on \( \mathbb{C}^2 \) by defining

\[
\rho(t) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \rho(c) = \begin{pmatrix} j & 0 \\ 0 & j^2 \end{pmatrix}.
\]

Definition 1.3. Let \( (|) \) be a scalar product on \( E \). We say that the representation \( \rho \) is unitary if \( \rho(g) \) is unitary for every \( g \), that is, if

\[
\forall g \in G, \forall x, y \in E, \quad (\rho(g)x | \rho(g)y) = (x | y).
\]

A representation \((E, \rho)\) is called unitarizable if there is a scalar product on \( E \) such that \( \rho \) is unitary.

In order to prove the following theorem, as well as many other propositions, we shall use a fundamental property:

Lemma 1.4. Let \( G \) be a finite group. For every function \( \varphi \) on \( G \) taking values in a vector space,

\[
\forall g \in G, \sum_{h \in G} \varphi(gh) = \sum_{h \in G} \varphi(hg) = \sum_{k \in G} \varphi(k). \quad (1.1)
\]

Proof. In fact, once \( g \) is chosen, every element of \( G \) can be written uniquely in the form \( gh \) (or \( hg \)), where \( h \in G \).

Theorem 1.5. Every representation of a finite group is unitarizable.

Proof. Let \((E, \rho)\) be a representation of a finite group \( G \), and let \( (|) \) be a scalar product on \( E \). We consider

\[
(x | y)' = \frac{1}{|G|} \sum_{g \in G} (\rho(g)x | \rho(g)y),
\]

which is a scalar product on \( E \). In fact, suppose that \((x | x)' = 0\), that is, \( \sum_{g \in G}(\rho(g)x | \rho(g)x) = 0 \). Then for each \( g \in G \), \((\rho(g)x | \rho(g)x) = 0 \), and in particular, \((x | x) = 0 \), whence \( x = 0 \).

This scalar product on \( E \) is invariant under \( \rho \). In fact,

\[
(\rho(g)x | \rho(g)y)' = \frac{1}{|G|} \sum_{h \in G} (\rho(h)\rho(g)x | \rho(h)\rho(g)y)
\]

\[
= \frac{1}{|G|} \sum_{h \in G} (\rho(hg)x | \rho(hg)y) = (x | y)',
\]

where we have used the fundamental equation \((1.1)\), which holds for any function \( \varphi \) on \( G \). Thus \( \rho \) is a unitary representation of \( G \) on \((E, (|)'\)).
1.2 Irreducible Representations

Let \((E, \rho)\) be a representation of \(G\). A vector subspace \(F \subset E\) is called invariant (or stable) under \(\rho\) (or under \(G\), if the name of the representation is understood) if for every \(g \in G\), \(\rho(g)F \subset F\). (since \(F\) is finite-dimensional, the condition \(\rho(g)F \subset F\) implies \(\rho(g)F = F\).) We can then speak of the representation \(\rho\) restricted to \(F\), which is a representation of \(G\) on \(F\). We denote it by \(\rho|_F\). Such a representation restricted to an invariant subspace is also called a subrepresentation.

**Definition 1.6.** A representation \((E, \rho)\) of \(G\) is called irreducible if \(E \neq \{0\}\) and if the only vector subspaces of \(E\) invariant under \(\rho\) are \(\{0\}\) and \(E\) itself.

**Example.** The representation of dimension 2 of \(S_3\) defined in Example 1.2 is irreducible, since the eigenspaces of \(\rho(t)\) and \(\rho(c)\) have trivial intersection.

**Proposition 1.7.** Every irreducible representation of a finite group is finite-dimensional.

**Proof.** Let \((E, \rho)\) be an irreducible representation of a finite group \(G\) and let \(x \in E\). Because the subset \(\{\rho(g)x \mid g \in G\}\) is finite, it generates a finite-dimensional vector subspace of \(E\). If \(x \neq 0\), this vector subspace of \(E\) is not equal to \(\{0\}\). Because this subspace is invariant under \(\rho\), it coincides with \(E\), which is thus finite-dimensional. \(\square\)

1.3 Direct Sum of Representations

**Definition 1.8.** Let \((E_1, \rho_1)\) and \((E_2, \rho_2)\) be representations of \(G\). Then

\[(E_1 \oplus E_2, \rho_1 \oplus \rho_2),\]

where \((\rho_1 \oplus \rho_2)(g)(x_1, x_2) = (\rho_1(g)(x_1), \rho_2(g)(x_2))\), for \(g \in G, x_1 \in E_1, x_2 \in E_2\), is a representation of \(G\) called the direct sum of the representations \((E_1, \rho_1)\) and \((E_2, \rho_2)\).

Clearly a direct sum of representations of strictly positive dimensions cannot be irreducible, even if the summands are irreducible. For matrix representations \(\rho_1\) and \(\rho_2\), the matrices of the direct sum representation of \(\rho_1\) and \(\rho_2\) are block-diagonal matrices

\[
\begin{pmatrix}
\rho_1(g) & 0 \\
0 & \rho_2(g)
\end{pmatrix},
\]

More generally, if \(m\) is a strictly positive integer, we can use recursion to define the direct sum of \(m\) representations \(\rho_1 \oplus \cdots \oplus \rho_m\). If \((E, \rho)\) is a representation of \(G\) we denote by \(mp\) the representation \(\rho \oplus \cdots \oplus \rho\) (direct sum of \(m\) terms) on the vector space \(E \oplus \cdots \oplus E\) (\(m\) terms).

A representation is called completely reducible if it is a direct sum of irreducible representations.
Lemma 1.9. Let \( \rho \) be a unitary representation of \( G \) on \((E, (\ | \ ))\). If \( F \subset E \) is invariant under \( \rho \), then \( F^\perp = \{ y \in E \mid \forall x \in F, (x \mid y) = 0 \} \) is also invariant under \( \rho \).

Proof. Let \( y \in F^\perp \). Then, because \( F \) is invariant under \( \rho \), for every \( g \in G \) and \( x \in F \), \((x \mid \rho(g)y) = (\rho(g^{-1})x \mid y) = 0\). Thus \( \rho(g)y \in F^\perp \).

\[ \square \]

Theorem 1.10 (Maschke’s Theorem). Every finite-dimensional representation of a finite group is completely reducible.

Proof. Let \((E, \rho)\) be a representation of \( G \). By Theorem 1.5, one may suppose this representation to be unitary. If \( \rho \) is not irreducible, let \( F \) be a vector subspace of \( E \) invariant under \( \rho \) such that \( F \neq \{0\} \) and \( F \neq E \). Then \( E = F \oplus F^\perp \), where \( F \) (by hypothesis) and \( F^\perp \) (by Lemma 1.9) are invariant under \( \rho \), and \( \dim F < \dim E \), \( \dim F^\perp < \dim E \). By induction on the dimension of \( E \), we obtain the desired result.

\[ \square \]

In fact, this theorem is true under more general conditions. (See the study of compact groups in Chapter 3.)

1.4 Intertwining Operators and Schur’s Lemma

Definition 1.11. Let \((E_1, \rho_1)\) and \((E_2, \rho_2)\) be representations of \( G \). We say that a linear map \( T : E_1 \to E_2 \) intertwines \( \rho_1 \) and \( \rho_2 \) if

\[ \forall g \in G, \ \rho_2(g) \circ T = T \circ \rho_1(g), \]

in which case \( T \) is called an intertwining operator for \( \rho_1 \) and \( \rho_2 \).

The definition can be expressed in the commutativity of the following diagram for each \( g \in G \):

\[
\begin{array}{ccc}
E_1 & \xrightarrow{T} & E_2 \\
\rho_1(g) \downarrow & & \downarrow \rho_2(g) \\
E_1 & \xrightarrow{T} & E_2
\end{array}
\]

The following expressions are often used to express the same property:

- \( T \) is equivariant under \( \rho_1 \) and \( \rho_2 \),
- \( T \) is a morphism of \( G \)-vector spaces,
- \( T \) is a \( G \)-morphism,
- \( T \in \text{Hom}_G(E_1, E_2) \).

If \( E_1 = E_2 = E \) and if \( \rho_1 = \rho_2 = \rho \), an intertwining operator for \( \rho_1 \) and \( \rho_2 \) is just an operator that commutes with \( \rho \).

Definition 1.12. The representations \( \rho_1 \) and \( \rho_2 \) are called equivalent if there is a bijective intertwining operator for \( \rho_1 \) and \( \rho_2 \).
If \( T \) is such a bijective intertwining operator, then
\[
\forall g \in G, \ \rho_2(g) = T \circ \rho_1(g) \circ T^{-1}.
\]
The existence of an intertwining operator is an equivalence relation on representations, which leads to the notion of an equivalence class of representations. We let \( \sim \) denote this equivalence relation.

Two representations \( (E_1, \rho_1) \) and \( (E_2, \rho_2) \) are equivalent if and only if there is a basis \( B_1 \) of \( E_1 \) and a basis \( B_2 \) of \( E_2 \) such that for every \( g \in G \), the matrix of \( \rho_1(g) \) in the basis \( B_1 \) is equal to the matrix of \( \rho_2(g) \) in the basis \( B_2 \). In particular, if the representations \( (E_1, \rho_1) \) and \( (E_2, \rho_2) \) are equivalent, then \( E_1 \) is isomorphic to \( E_2 \).

For equivalent matrix representations, we thus obtain similar matrices: if \( E_1 = E_2 = \mathbb{C}^n \), and if \( \rho_1 \) and \( \rho_2 \) are equivalent, then the matrices \( \rho_1(g) \) and \( \rho_2(g) \) are similar via the same similarity matrix for every \( g \).

If \( \rho_0 \) is an \( n \)-dimensional representation of \( G \) on \( E \), the choice of a basis \( (e_i) \) of \( E \) determines a matrix representation \( (\mathbb{C}^n, \rho) \); by changing to the basis \( (e'_i) \) via a matrix \( T \), one obtains the equivalent representation \( (\mathbb{C}^n, \rho') \),
\[
\rho'(g) = T \circ \rho(g) \circ T^{-1}.
\]

**Lemma 1.13.** If \( T \) intertwines \( \rho_1 \) and \( \rho_2 \), then the kernel of \( T \), \( \text{Ker} \ T \), is invariant under \( \rho_1 \), and the image of \( T \), \( \text{Im} \ T \), is invariant under \( \rho_2 \).

**Proof.** If \( x \in E_1 \) and \( Tx = 0 \), then \( T(\rho_1(g)x) = \rho_2(g)(Tx) = 0 \). Thus \( \text{Ker} \ T \) is a subspace of \( E_1 \) invariant under \( \rho_1 \).

Let \( y \in \text{Im} \ T \). Then, there exists \( x \in E_1 \) such that \( y = Tx \). Therefore \( \rho_2(g)y = \rho_2(g)(Tx) = T(\rho_1(g)x) \), and hence \( \text{Im} \ T \) is a subspace of \( E_2 \) invariant under \( \rho_2 \). \( \square \)

**Lemma 1.14.** If \( T \) commutes with \( \rho \), each eigenspace of \( T \) is invariant under \( \rho \).

**Proof.** In fact, if \( Tx = \lambda x, \lambda \in \mathbb{C} \), then \( T(\rho(g)x) = \lambda \rho(g)x \). Thus the eigenspace of \( T \) corresponding to the eigenvalue \( \lambda \) is invariant under \( \rho \). \( \square \)

**Theorem 1.15 (Schur’s Lemma).** Let \( T \) be an operator intertwining irreducible representations \( (E_1, \rho_1) \) and \( (E_2, \rho_2) \) of \( G \).

- If \( \rho_1 \) and \( \rho_2 \) are not equivalent, then \( T = 0 \).
- If \( E_1 = E_2 = E \) and \( \rho_1 = \rho_2 = \rho \), then \( T \) is a scalar multiple of the identity of \( E \).

**Proof.** If \( \rho_1 \) and \( \rho_2 \) are not equivalent, \( T \) is not bijective. Hence either \( \text{Ker} \ T \neq \{0\} \), or \( \text{Im} \ T \neq E_2 \). By Lemma 1.13, \( \text{Ker} \ T \) is invariant under \( \rho_1 \). Because \( \rho_1 \) is irreducible, if \( \text{Ker} \ T \neq \{0\} \), then \( \text{Ker} \ T = E_1 \); hence \( T = 0 \). By Lemma 1.13, \( \text{Im} \ T \) is invariant under \( \rho_2 \). Because \( \rho_2 \) is irreducible, if \( \text{Im} \ T \neq E_2 \), then \( \text{Im} \ T = \{0\} \), and hence \( T = 0 \).

If \( E_1 = E_2 = E \) and \( \rho_1 = \rho_2 = \rho \), then for every \( g \in G \), \( \rho(g) \circ T = T \circ \rho(g) \), and \( T \) commutes with the representation \( \rho \). Let \( \lambda \) be an eigenvalue of \( T \), which must exist because \( T \) is an endomorphism of \( E \), a vector space over \( \mathbb{C} \), and let
let $E_\lambda$ be the eigenspace associated to $\lambda$. By Lemma 1.14, $E_\lambda$ is invariant under $\rho$. By hypothesis $E_\lambda \neq \{0\}$, therefore, since $\rho$ is irreducible, $E_\lambda = E$, which means that $T = \lambda \text{Id}_E$. We remark that the proof of the second part of the theorem uses the hypothesis that the vector space of the representation is a complex vector space.

Conversely, if each operator commuting with the representation $\rho$ is a scalar multiple of the identity, then $\rho$ is irreducible. In fact, if $\rho$ were not irreducible, the projection onto a nontrivial invariant subspace would be a nonscalar operator commuting with $\rho$.

Remark. Lemma 1.14 has very important consequences in quantum mechanics. The symmetry operators of a system represented by a Hamiltonian $\hat{H}$ (an operator acting on a Hilbert space) are precisely the operators that commute with $\hat{H}$. For each energy level, that is, for each eigenvalue of the Hamiltonian, there is a corresponding eigenspace. By this lemma, each eigenspace is the support of a representation of the group of symmetries of the system. Wigner’s principle then states that for each energy level, the corresponding representation is an irreducible representation of the full symmetry group of the system. The dimension of the representation corresponding to the given energy level is called the degree of degeneracy of the energy level.

2 Characters and Orthogonality Relations

2.1 Functions on a Group, Matrix Coefficients

We shall denote by $\mathcal{F}(G)$, or sometimes by $\mathbb{C}[G]$, the vector space of functions on $G$ taking values in $\mathbb{C}$. When this vector space is equipped with the scalar product defined below, we call the resulting Hilbert space $L^2(G)$. (This definition will be extended to compact groups.)

We adopt the convention that a scalar product is antilinear in the first argument and linear in the second.

Definition 2.1. On $L^2(G)$, the scalar product is defined by

$$ (f_1 | f_2) = \frac{1}{|G|} \sum_{g \in G} \overline{f_1(g)} f_2(g). $$

We shall be interested in the matrix coefficients of representations.

Definition 2.2. If $\rho$ is a representation of $G$ on $\mathbb{C}^n$, then for every ordered pair $(i, j)$, $1 \leq i \leq n$, $1 \leq j \leq n$, the function $\rho_{ij} \in L^2(G)$ defined for each $g \in G$ to be the coefficient of the matrix $\rho(g)$ in the $i$th row and the $j$th column, $(\rho(g))_{ij} \in \mathbb{C}$, is called a matrix coefficient of $\rho$.

For a representation $\rho$ on a vector space $E$, we define the matrix coefficients $\rho_{ij}$ relative to a basis $(e_i)$ satisfying

$$ \rho(g)e_j = \sum_i \rho_{ij}(g)e_i, $$
where $i$ is the row index and $j$ is the column index. If $\rho$ is a unitary representation on a finite-dimensional Hilbert space, then

$$\rho(g^{-1}) = (\rho(g))^{-1} = \overline{t(\rho(g))}. $$

Hence, in an orthonormal basis,

$$\rho_{ij}(g^{-1}) = \rho_{ji}(g),$$

and in particular, the diagonal coefficients of $\rho(g)$ and $\rho(g^{-1})$ are complex conjugates.

### 2.2 Characters of Representations and Orthogonality Relations

We denote by $\text{Tr}$ the trace of an endomorphism.

**Definition 2.3.** Let $(E, \rho)$ be a representation of $G$. The character of $\rho$ is the function $\chi_{\rho}$ on $G$ taking complex values defined by

$$\forall g \in G, \chi_{\rho}(g) = \text{Tr}(\rho(g)).$$

Equivalent representations have the same character.

For a matrix representation of dimension $n$,

$$\chi_{\rho}(g) = \sum_{i=1}^{n} (\rho(g))_{ii}. \quad (2.1)$$

On each conjugacy class of $G$, the function $\chi_{\rho}$ is constant.

**Definition 2.4.** A class function on $G$ is a function constant on each conjugacy class.

Thus characters of representations are class functions on the group.

**Proposition 2.5.** The following are elementary properties of characters:

- $\chi_{\rho}(e) = \dim \rho$.
- $\forall g \in G, \chi_{\rho}(g^{-1}) = \chi_{\rho}(g)$.
- The character of a direct sum of representations is the sum of the characters, $\chi_{\rho_1 \oplus \rho_2} = \chi_{\rho_1} + \chi_{\rho_2}$.

**Proof.** The first property is a consequence of formula (2.1). To prove the second formula, we may assume that $\rho$ is unitary in a certain scalar product and choose an orthonormal basis. The direct sum property is obvious. \qed

If $(E_1, \rho_1)$ and $(E_2, \rho_2)$ are representations of the same group $G$, we define their tensor product to be $(E_1 \otimes E_2, \rho_1 \otimes \rho_2)$, where

$$(\rho_1 \otimes \rho_2)(g) = \rho_1(g) \otimes \rho_2(g),$$

for each $g \in G$. (See Exercise 2.5 for a review of the relevant definitions.) The following is an important property of characters.
Chapter 2 Representations of Finite Groups

Proposition 2.6. The character of a tensor product of representations is the product of the characters,
\[ \chi_{\rho_1 \otimes \rho_2} = \chi_{\rho_1} \chi_{\rho_2}. \] (2.2)

Proof. The equality follows from the fact that the trace of a tensor product of matrices is the product of the traces. □

By Proposition 2.5, for representations \( \rho_1 \) and \( \rho_2 \) of \( G \),
\[ (\chi_{\rho_1} | \chi_{\rho_2}) = \frac{1}{|G|} \sum_{g \in G} \chi_{\rho_1}(g^{-1})\chi_{\rho_2}(g). \] (2.3)

We shall show that the characters of inequivalent irreducible representations are orthogonal and that the character of an irreducible representation is of norm 1.

Proposition 2.7. Let \( (E_1, \rho_1) \) and \( (E_2, \rho_2) \) be representations of \( G \) and let \( u : E_1 \to E_2 \) be a linear map. Then the linear map \( T_u : E_1 \to E_2 \) defined by
\[ T_u = \frac{1}{|G|} \sum_{g \in G} \rho_2(g) \rho_1(g)^{-1} \] (2.4)
intertwines \( \rho_1 \) and \( \rho_2 \).

Proof. We calculate
\[ \rho_2(g) T_u = \frac{1}{|G|} \sum_{h \in G} \rho_2(gh) \rho_1(h^{-1}) = \frac{1}{|G|} \sum_{k \in G} \rho_2(k) \rho_1(k^{-1}g), \]
by the fundamental equation (1.1). Hence,
\[ \rho_2(g) T_u = T_u \rho_1(g). \]
The operator \( T_u \) is thus an intertwining operator for \( \rho_1 \) and \( \rho_2 \). □

Proposition 2.8. Let \( (E_1, \rho_1) \) and \( (E_2, \rho_2) \) be irreducible representations of \( G \), let \( u : E_1 \to E_2 \) be a linear map, and define \( T_u \) by equation (2.4).

(i) If \( \rho_1 \) and \( \rho_2 \) are inequivalent, then \( T_u = 0 \).

(ii) If \( E_1 = E_2 = E \) and \( \rho_1 = \rho_2 = \rho \), then
\[ T_u = \frac{\text{Tr } u}{\text{dim } E} \text{Id}_E. \]

Proof. The first assertion is clear by Schur’s lemma (Theorem 1.15). For the second, we need only calculate \( \lambda \) given that \( T_u = \lambda \text{Id}_E \). So we obtain
\[ \text{Tr } T_u = \frac{1}{|G|} \sum_{g \in G} \text{Tr } u = \text{Tr } u, \]
and thus \( \lambda = \frac{\text{Tr } u}{\text{dim } E} \). □
Proposition 2.9. Let \((E_1, \rho_1)\) and \((E_2, \rho_2)\) be irreducible representations of \(G\). We choose bases in \(E_1\) and \(E_2\).

(i) If \(\rho_1\) and \(\rho_2\) are inequivalent, then

\[
\forall i, j, k, \ell, \sum_{g \in G} (\rho_2(g))_{k\ell}(\rho_1(g^{-1}))_{ji} = 0.
\]

(ii) If \(E_1 = E_2 = E\) and \(\rho_1 = \rho_2 = \rho\), then

\[
\frac{1}{|G|} \sum_{g \in G} (\rho(g))_{k\ell}(\rho(g^{-1}))_{ji} = \frac{1}{\dim E} \delta_{ki} \delta_{\ell j}.
\]

Proof. We use a basis \((e_j)\) of \(E_1, 1 \leq j \leq \dim E_1\), and a basis \((f_\ell)\) of \(E_2, 1 \leq \ell \leq \dim E_2\). For \(u : E_1 \to E_2\), \(T_u\) is defined by (2.4). We have, for \(1 \leq i \leq \dim E_1, 1 \leq k \leq \dim E_2\),

\[
(T_u)_{ki} = \frac{1}{|G|} \sum_{g \in G} \dim E_1 \dim E_2 \sum_{m=1}^{\dim E_1} \sum_{p=1}^{\dim E_2} (\rho_2(g))_{kp} u_{pm} (\rho_1(g^{-1}))_{mi}.
\]

Let us choose our linear map \(u\) to be the map \(u(\ell j) : E_1 \to E_2\) defined by \(u(\ell j)(e_k) = \delta_{jk}f_\ell\). Then

\[
(u(\ell j))_{pm} = \delta_{\ell p} \delta_{jm},
\]

and consequently,

\[
(T_u(\ell j))_{ki} = \frac{1}{|G|} \sum_{g \in G} (\rho_2(g))_{k\ell}(\rho_1(g^{-1}))_{ji}.
\]

Next we apply Proposition 2.8. If \(\rho_1\) and \(\rho_2\) are inequivalent, then \(T_u(\ell j)\) is always zero, whence (i). If \(E_1 = E_2 = E\) and \(\rho_1 = \rho_2 = \rho\), then

\[
\frac{1}{|G|} \sum_{g \in G} (\rho(g))_{k\ell}(\rho(g^{-1}))_{ji} = (T_u(\ell j))_{ki} = \frac{\Tr u(\ell j)}{\dim E} \delta_{ki} = \frac{\delta_{ki} \delta_{\ell j}}{\dim E},
\]

which proves (ii). \(\Box\)

Corollary 2.10. Let \((E_1, \rho_1)\) and \((E_2, \rho_2)\) be unitary irreducible representations of \(G\). We choose orthonormal bases in \(E_1\) and \(E_2\).

(i) If \(\rho_1\) and \(\rho_2\) are inequivalent, then for every \(i, j, k, l\),

\[
((\rho_1)_{ij} | (\rho_2)_{k\ell}) = 0.
\]

(ii) If \(E_1 = E_2 = E\) and \(\rho_1 = \rho_2 = \rho\), then for every \(i, j, k, l\),

\[
(\rho_{ij} | \rho_{k\ell}) = \frac{1}{\dim E} \delta_{ik} \delta_{j\ell}.
\]
Proof. In fact, if \( \rho_1 \) is unitary for a scalar product on \( E_1 \) and if the chosen basis in \( E_1 \) is orthonormal, then

\[
\frac{1}{|G|} \sum_{g \in G} (\rho_2(g))_{k \ell} (\rho_1(g^{-1}))_{ji} = \frac{1}{|G|} \sum_{g \in G} (\rho_2(g))_{k \ell} (\rho_1(g))_{ij} = ((\rho_1)_{ij} \mid (\rho_2)_{k \ell}).
\]

Proposition 2.9 thus implies (i) and (ii). \( \square \)

**Theorem 2.11 (Orthogonality Relations).** Let \( G \) be a finite group.

(i) If \( \rho_1 \) and \( \rho_2 \) are inequivalent irreducible representations of \( G \), then

\[
(\chi_{\rho_1} \mid \chi_{\rho_2}) = 0.
\]

(ii) If \( \rho \) is an irreducible representation of \( G \), then

\[
(\chi_{\rho} \mid \chi_{\rho}) = 1.
\]

**Proof.** By the equality (2.3) and the preceding proposition, if \( \rho_1 \) and \( \rho_2 \) are inequivalent irreducible representations, then \( (\chi_{\rho_1} \mid \chi_{\rho_2}) = 0 \). If \( \rho_1 = \rho_2 = \rho \), then

\[
\frac{1}{|G|} \sum_{g \in G} \rho(g)_{ii} \rho(g^{-1})_{jj} = \frac{\delta_{ij}}{\dim E},
\]

whence \( (\chi_{\rho} \mid \chi_{\rho}) = 1 \). \( \square \)

We define the irreducible characters of \( G \) to be the set of characters of inequivalent irreducible representations of \( G \). We write \( \chi_{\rho_i} \) or even \( \chi_i \) to denote the character of an irreducible representation \( \rho_i \). The preceding results can be formulated as follows.

**Theorem 2.12.** The irreducible characters of \( G \) form an orthonormal set in \( L^2(G) \).

**Corollary 2.13.** The inequivalent irreducible representations of a finite group \( G \) are finite in number.

We shall denote by \( \hat{G} \) the set of equivalence classes of irreducible representations of \( G \).

### 2.3 Character Table

“Character table” is the name given to the table whose columns correspond to conjugacy classes of a group and whose rows correspond to inequivalent irreducible representations of the group. At the intersection of the row and the column one writes the value of the character of the representation, evaluated on an element (any element) of the conjugacy class. Let \( N \) be the number of conjugacy classes of the group \( G \). (In other words, \( N \) is the number of columns; we shall show that it is also the number of rows.) Let \( g_i \) be an element of \( G \) in the conjugacy class \( C_{g_i} \), \( 1 \leq i \leq N \), which consists of \( |C_{g_i}| \) elements. Let \( \rho_k \) and \( \rho_\ell \) be irreducible representations of \( G \). Then

\[
(\chi_{\rho_k} \mid \chi_{\rho_\ell}) = \frac{1}{|G|} \sum_{i=1}^{N} |C_{g_i}| \overline{\chi_{\rho_k}(g_i)} \chi_{\rho_\ell}(g_i) = \delta_{k \ell}.
\]

This formula can be restated as the following result.
Proposition 2.14. If the $i$th column is given weight $|C_{g_i}|$, the rows of the character table are orthogonal and of norm $\sqrt{|G|}$.

We write character tables in the following form:

$$
\begin{array}{c|c|c|c|}
|C_{g_1}| & \ldots & |C_{g_N}| \\
\hline
\ldots & \ldots & \ldots \\
\chi_{\rho_k} & \chi_{\rho_k}(g_1) & \ldots & \chi_{\rho_k}(g_N) \\
\ldots & \ldots & \ldots \\
\chi_{\rho_\ell} & \chi_{\rho_\ell}(g_1) & \ldots & \chi_{\rho_\ell}(g_N) \\
\ldots & \ldots & \ldots & \ldots 
\end{array}
$$

2.4 Application to the Decomposition of Representations

We denote by $\rho_1, \ldots, \rho_N$ the inequivalent irreducible representations of $G$. (We shall see in Corollary 3.7 that this number $N$ equals the number of conjugacy classes of $G$.) More precisely, we choose from each equivalence class of representations of $G$ a representative that we denote by $\rho_i$.

In the equalities below, the equal sign denotes membership in the same equivalence class.

Theorem 2.15. Let $\rho$ be any representation of $G$ and let $\chi_\rho$ be its character. Then

$$\rho = \bigoplus_{i=1}^{N} m_i \rho_i,$$

where

$$m_i = (\chi_{\rho_i} \mid \chi_\rho).$$

Proof. We know by Theorem 1.10 that $\rho$ is direct sum of irreducible representations. We can group the terms corresponding to the same equivalence class of irreducible representations $\rho_i$, and we obtain $\rho = \bigoplus_{i=1}^{N} m_i \rho_i$, for some nonnegative integers $m_i$. One sees then that $\chi_\rho = \sum_{i=1}^{N} m_i \chi_{\rho_i}$, and hence by orthogonality $(\chi_{\rho_i} \mid \chi_\rho) = m_i (\chi_{\rho_i} \mid \chi_{\rho_i}) = m_i$. \qed

Definition 2.16. If $\rho$ admits the decomposition

$$\rho = m_1 \rho_1 \oplus m_2 \rho_2 \oplus \cdots \oplus m_N \rho_N,$$

then the nonnegative integer $m_i$ is the multiplicity of $\rho_i$ in $\rho$, and $m_i \rho_i$ is the isotypic component of type $\rho_i$ of $\rho$.

Corollary 2.17. The decomposition into isotypic components is unique up to order.

Corollary 2.18. Two representations with the same character are equivalent.
By the previous theorem,

\[(\chi_\rho \mid \chi_\rho) = \sum_{i=1}^{N} m_i^2.\]

Hence we have the following result.

**Theorem 2.19 (Irreducibility Criterion).** A representation \(\rho\) is irreducible if and only if \((\chi_\rho \mid \chi_\rho) = 1\).

### 3 The Regular Representation

#### 3.1 Definition

In general, if a group \(G\) acts on a set \(M\), then \(G\) acts linearly on the space \(\mathcal{F}(M)\) of functions on \(M\) taking values in \(\mathbb{C}\) by \((g, f) \in G \times \mathcal{F}(M) \mapsto g \cdot f \in \mathcal{F}(M)\), where

\[\forall x \in M, \quad (g \cdot f)(x) = f(g^{-1}x).\]

We can see immediately that this gives us a representation of \(G\) on \(\mathcal{F}(M)\).

Take \(M = G\), the group acting on itself by left multiplication. One obtains a representation \(R\) of \(G\) on \(\mathcal{F}(G)\) called the left regular representation (or simply regular representation) of \(G\). Thus, by definition,

\[\forall g, h \in G, \quad (R(g)f)(h) = f(g^{-1}h).\]

In the same way one can define the right regular representation \(R'\), associated to the right action of \(G\) on itself, by \((R'(g)f)(h) = f(hg)\). The right and left regular representations are equivalent. For a finite group \(G\) the vector space \(\mathcal{F}(G)\) of maps of \(G\) into \(\mathbb{C}\) is finite-dimensional, of dimension \(|G|\). The regular representation is thus of dimension \(|G|\).

We use the basis \((\epsilon_g)_{g \in G}\) of \(\mathcal{F}(G)\) defined by

\[\epsilon_g : G \rightarrow \mathbb{C} \begin{cases} 
\epsilon_g(g) = 1, \\
\epsilon_g(h) = 0, \text{ if } h \neq g.
\end{cases}\]

The regular representation of \(G\) satisfies

\[\forall g, h \in G, \quad R(g)(\epsilon_h) = \epsilon_{gh}.\]

In fact, for every \(k \in G\), \((R(g)\epsilon_h)(k) = \epsilon_h(g^{-1}k)\), and \(\epsilon_h(g^{-1}k) = 1\) if \(k = gh\), while \(\epsilon_h(g^{-1}k) = 0\) otherwise. (In the right regular representation, \(\epsilon_h \mapsto \epsilon_{hg^{-1}}\)).

**Proposition 3.1.** On \(L^2(G) = \mathcal{F}(G)\) with scalar product \((\mid \cdot \cdot)\), the regular representation is unitary.
Proof. For \( f_1 \) and \( f_2 \in L^2(G) \) we have, for every \( g \in G \),

\[
(R(g)f_1 \mid R(g)f_2) = \frac{1}{|G|} \sum_{h \in G} (R(g)f_1)(h)(R(g)f_2)(h)
\]

\[
= \frac{1}{|G|} \sum_{h \in G} f_1(g^{-1}h)f_2(g^{-1}h)
\]

\[
= \frac{1}{|G|} \sum_{k \in G} f_1(k)f_2(k) = (f_1 \mid f_2).
\]

The operator \( R(g) \) is thus unitary for every \( g \in G \). \( \square \)

3.2 Character of the Regular Representation

On the one hand,

\[
\chi_R(e) = \text{Tr}(R(e)) = \dim \mathcal{F}(G) = |G|.
\]

On the other hand, if \( g \neq e \), then

\[
\chi_R(g) = \text{Tr}(R(g)) = 0
\]
because in this case, for every \( h \in G \), \( R(g)\epsilon_h \neq \epsilon_h \).

The regular representation \( R \) is reducible because \( \sum_{g \in G} \epsilon_g \) generates a vector subspace \( W \) of \( \mathcal{F}(G) \) of dimension 1 that is invariant under \( R \). In fact, for every \( g \in G \), \( R(g)(\sum_{h \in G} \epsilon_h) = \sum_{h \in G} \epsilon_{gh} = \sum_{k \in G} \epsilon_k \). Furthermore, \( R \mid_W \) is equivalent to the trivial representation, since for every \( x \in W \), \( R(g)(x) = x \).

We shall show that, in fact, the regular representation contains each irreducible representation of \( G \) with multiplicity equal to its dimension.

Example 3.2. The regular representation of \( S_3 \) on \( \mathbb{C}[S_3] \) is of dimension 6. It decomposes into the direct sum of the one-dimensional trivial representation, the one-dimensional sign representation, and two copies of the two-dimensional irreducible representation studied in Example 1.2.

3.3 Isotypic Decomposition

We now use the notation introduced in Section 2.4.

Proposition 3.3. The decomposition of the regular representation of \( G \) into isotypic components is \( R = \bigoplus_{i=1}^N n_i \rho_i \), where \( \rho_i, i = 1, \ldots, N \), are the irreducible representations of \( G \), and \( n_i = \dim \rho_i \).

Proof. We know that

\[
\chi_R(g) = \begin{cases} |G| & \text{if } g = e, \\ 0 & \text{if } g \neq e, \end{cases}
\]

and hence \( (\chi_{\rho_i} \mid \chi_R) = \chi_{\rho_i}(e) = \dim \rho_i \). \( \square \)
Theorem 3.4. We have
\[ \sum_{i=1}^{N} (n_i)^2 = |G|, \]
where \( n_i = \text{dim} \rho_i \).

Proof. We have \(|G| = \chi_R(e) = \sum_{i=1}^{N} n_i \chi_{\rho_i}(e) = \sum_{i=1}^{N} (n_i)^2 \).

The equality \( \sum_{i=1}^{N} (n_i)^2 = |G| \) is often used, for example, in order to determine the dimension of a “missing” irreducible representation when one already knows \( N - 1 \) representations.

3.4 Basis of the Vector Space of Class Functions

The vector space of class functions on \( G \) taking values in \( \mathbb{C} \) has for dimension the number of conjugacy classes of \( G \). We shall show that this is also the number of equivalence classes of irreducible representations.

Let \((E,\rho)\) be a representation of \( G \), and let \( f \) be a function on \( G \).

We consider the endomorphism \( \rho_f \) of \( E \) defined by
\[ \rho_f = \sum_{g \in G} f(g)\rho(g). \quad (3.1) \]

Thus, by definition, for every \( x \in E \), \( \rho_f(x) = \sum_{g \in G} f(g)\rho(g)(x) \).

Lemma 3.5. The endomorphism \( \rho_f \) has the following properties:

(i) If \( f \) is a class function, \( \rho_f \) commutes with \( \rho \).

(ii) If \( f \) is a class function and if \( \rho \) is irreducible, then
\[ \rho_f = \frac{|G|\langle \overline{f} \mid \chi_{\rho} \rangle}{\text{dim} \rho} \text{Id}_E. \]

Proof. For every function \( f \), we have
\[ \rho_f \circ \rho(g) = \sum_{h \in G} f(h)\rho(h)\rho(g) = \sum_{h \in G} f(h)\rho(hg) = \sum_{k \in G} f(kg^{-1})\rho(k) = \sum_{h \in G} f(ghg^{-1})\rho(gh). \]

If \( f \) is assumed to be a class function, we obtain
\[ \rho_f \circ \rho(g) = \rho(g)\sum_{h \in G} f(h)\rho(h) = \rho(g) \circ \rho_f. \]

Let us prove (ii). By (i) and Schur’s lemma (Theorem 1.15), there is a \( \lambda \in \mathbb{C} \) such that \( \rho_f = \lambda \text{Id}_E \). On the other hand, \( \text{Tr} \rho_f = \sum_{g \in G} f(g)\text{Tr} \rho(g) = \sum_{g \in G} f(g)\chi_{\rho}(g) = |G|\langle \overline{f} \mid \chi_{\rho} \rangle \), from which the result follows. \( \square \)
Theorem 3.6. The irreducible characters form an orthonormal basis of the vector space of class functions.

Proof. We know that the characters $\rho_1, \ldots, \rho_N$ of inequivalent irreducible representations of $G$ form an orthonormal set in $L^2(G)$ (Theorem 2.12). Let us show that this set spans the vector subspace of class functions. Let $f$ be a class function such that for $1 \leq i \leq N$, $(f|\chi_{\rho_i}) = 0$. We consider $(\rho_i)_T = \sum_{g \in G} \overline{\chi}(g)\rho_i(g)$. By the previous lemma, $(\rho_i)_T = 0$, and we deduce, by decomposition, that for any representation $\rho$ we have $\rho_T = 0$. In particular, $R_T = 0$, where $R$ is the regular representation. Thus,

$$0 = R_T(\varepsilon_g) = \sum_{h \in G} \overline{\chi}(h)R(h)(\varepsilon_g) = \sum_{h \in G} \overline{\chi}(h)\varepsilon_{h_g},$$

for $g \in G$, and, in particular,

$$0 = R_T(\varepsilon_e) = \sum_{h \in G} \overline{\chi}(h)\varepsilon_h = \overline{\chi},$$

so $f = 0$. □

Corollary 3.7. The number of equivalence classes of irreducible representations of a finite group is equal to the number of conjugacy classes of that group.

In other words, the character table is square.

Proposition 3.8. The columns of the character table of a finite group $G$ are orthogonal and of norm $\sqrt{|G|/|C_g|}$, where $|C_g|$ denotes the number of elements of the conjugacy class of $g$. Explicitly,

$$\sum_{i=1}^N \overline{\chi}(g)\chi_{\rho_i}(g') = 0, \text{ if } g \text{ and } g' \text{ are not conjugate},$$

$$\frac{1}{|G|} \sum_{i=1}^N \chi_{\rho_i}(g)\chi_{\rho_i}(g) = \frac{1}{|C_g|}.$$ 

In particular, when $g = e$, we recover the equation $\sum_{i=1}^N (\dim \rho_i)^2 = |G|$.

Proof. By Theorem 3.6, if $f$ is a class function, then

$$f = \sum_{i=1}^N (\chi_{\rho_i} | f)\chi_{\rho_i}.$$ 

For $g \in G$, consider the class function $f_g$ that takes the value 1 on $g$ and the value 0 on every other conjugacy class of $G$. We have

$$(\chi_{\rho_i} | f_g) = \frac{1}{|G|} \sum_{h \in G} \chi_{\rho_i}(h)f_g(h) = \frac{|C_g|}{|G|} \chi_{\rho_i}(g),$$
and thus \( f_g = \frac{|C_g|}{|G|} \sum_{i=1}^{N} \chi_{\rho_i}(g) \chi_{\rho_i} \). In particular, if \( g' \not\in C_g \), then

\[
0 = f_g(g') = \frac{|C_g|}{|G|} \sum_{i=1}^{N} \chi_{\rho_i}(g) \chi_{\rho_i}(g'),
\]

which proves the first formula and hence the orthogonality of the columns of the character table. On the other hand, \( 1 = f_g(g) = \frac{|C_g|}{|G|} \sum_{i=1}^{N} \chi_{\rho_i}(g) \chi_{\rho_i}(g) \), which proves the second formula. \( \square \)

### 4 Projection Operators

We introduce the projection operators onto the isotypic components of the decomposition of the vector space of any representation. Let \((E, \rho)\) be a representation of \( G \) and let \( \rho = \oplus_{i=1}^{N} m_i \rho_i \) be the decomposition of \( \rho \) into isotypic components. The support of the isotypic component \( m_i \rho_i \) is \( m_i E_i = \oplus_{j=1}^{m_i} E_{i,j} \) (\( m_i \) terms). We denote this vector subspace of \( E \) by \( V_i \). We shall write

\[
V_i = m_i E_i = \oplus_{j=1}^{m_i} E_{i,j},
\]

where each \( E_{i,j} \), \( 1 \leq j \leq m_i \), is equal to \( E_i \). We thus have \( E = \oplus_{i=1}^{N} V_i \).

**Theorem 4.1.** For each \( i, 1 \leq i \leq N \), we set

\[
P_i = \frac{\dim \rho_i}{|G|} \sum_{g \in G} \chi_i(g) \rho(g).
\]

Then

(i) \( P_i \) is the projection of \( E \) onto \( V_i \) under the decomposition \( E = \oplus_{i=1}^{N} V_i \).

(ii) \( P_i P_j = \delta_{ij} P_i \), for \( 1 \leq i \leq N, 1 \leq j \leq N \).

(iii) If \( \rho \) is unitary, then \( P_i \) is Hermitian, that is, \( \overline{P_i} = P_i \).

**Proof.** (i) Let us choose \( i_0, 1 \leq i_0 \leq N \), and show that \( P_{i_0}|_{V_{i_0}} = Id_{V_{i_0}} \), while if \( i \neq i_0 \), then \( P_{i_0}|_{V_i} = 0 \). Let \( x = \sum_{i=1}^{N} x_i \), where \( x_i \in V_i \), and let \( x = \sum_{j=1}^{m_i} x_{i,j} \), where \( x_{i,j} \in E_{i,j} \), whence \( x = \sum_{i=1}^{N} \sum_{j=1}^{m_i} x_{i,j} \). Then

\[
P_{i_0}(x) = \frac{\dim \rho_{i_0}}{|G|} \sum_{i=1}^{N} \sum_{j=1}^{m_i} \sum_{g \in G} \chi_{i_0}(g) \rho(g) x_{i,j}
= \frac{\dim \rho_{i_0}}{|G|} \sum_{i=1}^{N} \sum_{j=1}^{m_i} \left( \sum_{g \in G} \chi_{i_0}(g) \rho_i(g) \right) x_{i,j}.
\]

Because \( \chi_{i_0} \) is a class function and \( \rho_i \) is irreducible, we may apply Lemma 3.5, and we obtain

\[
\sum_{g \in G} \chi_{i_0}(g) \rho_i(g) = \rho_i, \chi_{i_0} = \frac{|G|}{\dim \rho_i} (\chi_{i_0} | \chi_i) \text{Id}_{E_i} = \frac{|G|}{\dim \rho_{i_0}} \delta_{i_0} \text{Id}_{E_{i_0}},
\]
which finally leads to

\[ P_{i0}(x) = \sum_{i=1}^{N} \sum_{j=1}^{m_i} \delta_{i0} i_{x,i,j} = \sum_{j=1}^{m_{i0}} x_{i0,j} = x_{i0}. \]

(ii) The equations \( P_i P_j = 0 \) if \( i \neq j \) and \( P_i^2 = P_i \) follow from (i).

(iii) If \( \rho \) is unitary, then

\[ \frac{|G|}{\dim \rho_i} \sum_{g \in G} \chi_i(g)^t \rho(g) = \sum_{g \in G} \chi_i(g) \rho(g^{-1}) \]

\[ = \sum_{g \in G} \chi_i(g^{-1}) \rho(g) = \sum_{g \in G} \chi_i(g) \rho_i(g), \]

which is equal to \( \frac{|G|}{\dim \rho_i} P_i \), which proves (iii).

The decomposition \( E = \oplus_{i=1}^{N} V_i \) is unique up to order. On the other hand, the decomposition \( V_i = \oplus_{j=1}^{m_i} E_{i,j} \) is not always unique. For example, if \( \rho = \text{Id}_E \), then \( \rho \) can be written in an infinite number of ways as a direct sum of one-dimensional representations.

5 Induced Representations

Induction is an operation that associates to a representation of a subgroup \( H \) of a group \( G \) a representation of the group \( G \) itself.

5.1 Definition

Let \( G \) be a finite group and \( H \) a subgroup. Let \((F, \pi)\) be a representation of \( H \). We define the vector space

\[ E = \{ \varphi : G \rightarrow F \mid \forall h \in H, \varphi(gh) = \pi(h^{-1}) \varphi(g) \}, \tag{5.1} \]

and a representation \( \rho = \pi^{\uparrow G} \) of \( G \) on \( E \) by

\[ \forall \varphi \in E, \quad (\rho(g_0)\varphi)(g) = \varphi(g_0^{-1}g), \tag{5.2} \]

for every \( g_0 \in G \) and for every \( g \in G \). We can see that \( \rho(g_0)\varphi \) lies in \( E \) because

\[ (\rho(g_0)\varphi)(gh) = \varphi(g_0^{-1}gh) = \pi(h^{-1}) \varphi(g_0^{-1}g) = \pi(h^{-1}) ((\rho(g_0)\varphi)(g)), \]

and on the other hand, we see that \( g \mapsto \rho(g) \) is a group morphism of \( G \) into \( \text{GL}(E) \).

Definition 5.1. The representation \( \rho = \pi^{\uparrow G} \) of \( G \) on \( E \) is called the representation of \( G \) induced from the representation \( \pi \) of the subgroup \( H \) of \( G \).

For example, if \( H = \{e\} \) and if \( \pi \) is the trivial representation of \( H \) on \( \mathbb{C} \), then the vector space \( E \) is equal to \( \mathbb{C}[G] \) and the representation of \( G \) induced from \( \pi \) is the regular representation of \( G \).
5.2 Geometric Interpretation

We can interpret the vector space $E$ as the space of sections of a “vector bundle.”

We consider the Cartesian product $G \times F$ and we introduce the equivalence relation

$$ (g, x) \sim (gh, \pi(h^{-1})x), \quad \forall h \in H. \quad (5.3) $$

Let $G \times_{\pi} F$ be the quotient of $G \times F$ by this equivalence relation, and let

$$ q : G \times_{\pi} F \to G/H $$

be the projection that sends the equivalence class of $(g, x)$ to $gH$. Note that this is well defined, because if $(g', x') \sim (g, x)$, then $g' = gh$, for some $h \in H$. The inverse image under the projection $q$ of any point in $G/H$ is isomorphic to the vector space $F$. We call $G \times_{\pi} F$ a vector bundle over $G/H$ with fiber $F$.

A section of the projection $q : G \times_{\pi} F \to G/H$ (or of the vector bundle $G \times_{\pi} F$) is, by definition, a map $\psi$ from $G/H$ to $G \times_{\pi} F$ such that $q \circ \psi = \text{Id}_{G/H}$.

**Proposition 5.2.** The support $E$ of the induced representation $\pi^G$ is the vector space of sections of the projection $q : G \times_{\pi} F \to G/H$.

**Proof.** To $\varphi \in E$ and $g \in G$ we associate the equivalence class of $(g, \varphi(g))$. The result depends only on the class of $g$ modulo $H$. In fact, if $g' = gh$, with $h \in H$, we obtain the equivalence class of $(gh, \varphi(gh))$, which is equal to the equivalence class of $(g, \pi(h)\varphi(gh)) = (g, \varphi(g))$, since $\varphi \in E$. Thus one defines a section of $q : G \times_{\pi} F \to G/H$. On the other hand, to any given section of $q$ we may associate an element of $E$ by considering the second component of the equivalence class associated to an element of $G/H$. Since this construction is the inverse of the previous one, we have thus obtained an isomorphism of the space $E$ of the induced representation onto the vector space of sections of the vector bundle $G \times_{\pi} F$.

The notion of an induced representation can be defined more generally than just for finite groups, and has many applications in mathematics and physics.

**References**

The representations of finite groups are the subject of Serre’s book (1997), of which Part I is an exposition of fundamental results. Finite groups are studied in Sternberg (1994), Simon (1996), Artin (1991) and Ledermann–Weir (1996). Also see the first chapters of Fulton–Harris (1991), which are followed by chapters on Lie algebra representations, or the textbook by James and Liebeck (1993, 2001), which stresses arithmetic. All of these works discuss induced representations. For applications to physics, see Ludwig–Falter (1996), Tung (1985), or Blaizot–Tolédano (1997).

Tensor products of vector spaces are introduced in Exercise 2.5 below. (Also see Exercise 2.7.) For supplementary material on the tensor, exterior, and symmetric algebras of a vector space, see Greub (1967), Warner (1983), Sternberg (1994), or Knapp (2002).
The theory of characters was created by Frobenius in a series of articles published, starting in 1896, in the *Sitzungsberichte* of the Berlin Academy. These articles, reprinted in Frobenius (1968), contain beautiful character tables, p. 345, for a subgroup of $S_{12}$ of order $12 \cdot 11 \cdot 10 \cdot 9 \cdot 8$ with 15 irreducible representations, and, on the folding page between p. 346 and p. 347, for a subgroup of $S_{24}$ of order $24 \cdot 23 \cdot 22 \cdot 21 \cdot 20 \cdot 48$ with 26 irreducible representations. One can find a historical and mathematical analysis of this theory in the book by Curtis (1999). Also see Hawkins (2000) and Rossmann (2002).

Heinrich Maschke (1858–1908) published the theorem that bears his name in 1899, as a preliminary result in an attempt to prove a property of finite groups of matrices with complex coefficients.

For an in-depth study of induced representations, including those of Lie groups, see, e.g., Gurarie (1992), which includes applications to physics.

**Exercises**

**Exercise 2.1** *The symmetric group $S_3$.*

We write $c$ for the cyclic permutation $(123)$ and $t$ for the transposition $(23)$. Show that $\{c, t\}$ generates $S_3$, and that $tc = c^2t$, $ct = tc^2$. Find the conjugacy classes of the group $S_3$.

**Exercise 2.2** *Representations of $S_3$.*

(a) Find the one-dimensional representations of the group $S_3$.
(b) Let $e_1, e_2, e_3$ be the canonical basis of $\mathbb{C}^3$. For $g \in S_3$, set $\sigma(g)e_i = e_{g(i)}$. Show that this defines a three-dimensional representation $\sigma$ of $S_3$ and that $V = \{(z_1, z_2, z_3) \in \mathbb{C}^3 \mid z_1 + z_2 + z_3 = 0\}$ is invariant under $\sigma$. This representation is called the *permutation representation* of the symmetric group.

We denote by $\rho$ the restriction to $V$ of the representation $\sigma$.
(c) Show that there is a basis $(u_1, u_2)$ of $V$ such that $\rho(t)u_1 = u_2$, $\rho(t)u_2 = u_1$, $\rho(c)u_1 = ju_1$, $\rho(c)u_2 = j^2u_2$, where $j^2 + j + 1 = 0$. Is the representation $\rho$ irreducible?
(d) Find the character table of $S_3$.
(e) What is the geometric interpretation of $S_3$ as a group of symmetries? What is the geometric interpretation of the representation $\rho$?

**Exercise 2.3** *The symmetric group $S_4$.*

Find the conjugacy classes and character table of the symmetric group $S_4$.

**Exercise 2.4** *The alternate group $A_4$.*

Find the character table of $A_4$. Which representations of $A_4$ are the restriction of a representation of $S_4$? Which representations of $S_4$ have an irreducible restriction to $A_4$? Which have a reducible restriction?
Exercise 2.5 Tensor products of vector spaces and of representations.

We denote the dual of a vector space $E$ by $E^*$, and the duality pairing by $\langle \cdot, \cdot \rangle$.

If $E$ and $F$ are finite-dimensional vector spaces over $\mathbb{K}$ (where $\mathbb{K} = \mathbb{R}$ or $\mathbb{C}$), one can define the tensor product $E \otimes F$ as the vector space of bilinear maps of $E^* \times F^*$ into the scalar field $\mathbb{K}$. For $x \in E, y \in F$, we define the element $x \otimes y \in E \otimes F$ by

$$\langle x \otimes y)(\xi, \eta) = \langle \xi, x \rangle \langle \eta, y \rangle,$$

for every $\xi \in E^*, \eta \in F^*$.

(a) Let $(e_1, \ldots, e_n)$ be a basis of $E$ and let $(f_1, \ldots, f_p)$ be a basis of $F$. Show that $(e_i \otimes f_j)_{1 \leq i \leq n, 1 \leq j \leq p}$ is a basis of $E \otimes F$.

(b) An element of $E \otimes E$ is called a contravariant tensor (or simply a tensor) of order 2 on $E$. Every contravariant tensor of order 2 on $E$ can be written $T = \sum_{i,j=1}^n T^{ij} e_i \otimes e_j$, where the $T^{ij}$ are scalars, called the components of $T$ in the basis $(e_i)$. What are the components of $T$ after a change of basis?

(c) We can associate to $\xi \otimes y \in E^* \otimes F$ the linear map $u$ of $E$ into $F$ defined by $u(x) = \langle \xi, x \rangle y$, for $x \in E$. Show that this defines an isomorphism of $E^* \otimes F$ onto the vector space of linear maps of $E$ into $F$, $\mathcal{L}(E, F)$.

(d) Show that if $u : E \rightarrow E$ and $v : F \rightarrow F$ are linear maps, then there is a unique endomorphism $u \otimes v$ of $E \otimes F$ satisfying $(u \otimes v)(x \otimes y) = u(x) \otimes v(y)$ for each $x \in E, y \in F$. In $E \otimes F$, we choose the basis

$$(e_1 \otimes f_1, e_1 \otimes f_2, \ldots, e_1 \otimes f_p, e_2 \otimes f_1, e_2 \otimes f_2, \ldots, e_2 \otimes f_p, \ldots, e_n \otimes f_1, \ldots, e_n \otimes f_p).$$

Write the matrix of $u \otimes v$, where $u$ (respectively, $v$) is an endomorphism of $E$ (respectively, $F$) with matrix $A = (a_{ij})$ (respectively, $B = (b_{ij})$) in the chosen bases.

(e) If $(E_1, \rho_1)$ and $(E_2, \rho_2)$ are representations of a group $G$, we set, for $g \in G$, $(\rho_1 \otimes \rho_2)(g) = \rho_1(g) \otimes \rho_2(g)$.

Show that this defines a representation $\rho_1 \otimes \rho_2$ of $G$ on $E_1 \otimes E_2$. What can one say about the character of $\rho_1 \otimes \rho_2$? If $\rho_1$ and $\rho_2$ are irreducible, is the representation $\rho_1 \otimes \rho_2$ irreducible?

Exercise 2.6 The dual representation.

Let $(E, \pi)$ be a representation of a group $G$. For $g \in G$, $\xi \in E^*$, $x \in E$, we set $\langle \pi^*(g)(\xi), x \rangle = \langle \xi, \pi(g^{-1})(x) \rangle$. (As in Excercise 2.5, $E^*$ is the dual of $E$, and $\langle \cdot, \cdot \rangle$ is the duality pairing.)

(a) Show that this defines a representation $\pi^*$ of $G$ on $E^*$. The representation $\pi^*$ is called the dual (or contragredient) of $\pi$.

(b) Show that if $(E, \pi)$ and $(F, \rho)$ are representations of a group $G$, then $g \cdot u = \rho(g) \circ u \circ \pi(g^{-1})$, for $u \in \mathcal{L}(E, F)$ and $g \in G$, defines a representation of $G$ on $\mathcal{L}(E, F)$, equivalent to $\pi^* \otimes \rho$. 

**Exercise 2.7** Exterior and symmetric powers.

Let $E$ be a finite-dimensional vector space, with basis $(e_1, \ldots, e_n)$. We denote by $\bigwedge^2 E$ (respectively, $S^2 E$) the vector subspace of $E \otimes E$ generated by $e_i \otimes e_j - e_j \otimes e_i$, $1 \leq i < j \leq n$ (respectively, $e_i \otimes e_j + e_j \otimes e_i$, $1 \leq i \leq j \leq n$). These definitions are independent of the choice of basis and $E \otimes E = \bigwedge^2 E \oplus S^2 E$.

The space $\bigwedge^2 E$ is the exterior (or antisymmetric) power of degree 2 of $E$, and the space $S^2 E$ is the symmetric power of degree 2 of $E$.

(a) If $(E, \rho)$ is a representation of a group $G$, then $\bigwedge^2 E$ and $S^2 E$ are invariant under $\rho \otimes \rho$. We denote the restriction of $\rho \otimes \rho$ to $\bigwedge^2 E$ (respectively, $S^2 E$) by $\bigwedge^2 \rho$ (respectively, $S^2 \rho$). Suppose that $G$ is finite. Show that the characters of these representations satisfy, for each $g \in G$,

$$\chi_{\bigwedge^2 \rho}(g) = \frac{1}{2} \left( (\chi_{\rho}(g))^2 - \chi_{\rho}(g^2) \right), \quad \chi_{S^2 \rho}(g) = \frac{1}{2} \left( (\chi_{\rho}(g))^2 + \chi_{\rho}(g^2) \right).$$

(b) If $\rho$ is the two-dimensional irreducible representation of $S_3$, find $\chi_{\bigwedge^2 \rho}$ and $\chi_{S^2 \rho}$. Decompose $\rho \otimes \rho$ into a direct sum of irreducible representations.

**Exercise 2.8** Equivalence of the left and right regular representations.

Show that the left and right regular representations of a finite group are equivalent.

**Exercise 2.9** Representations of abelian and cyclic groups.

(a) Show that every irreducible representation of a finite group is one-dimensional if and only if the group is abelian.

(b) Find all the inequivalent irreducible representations of the cyclic group of order $n$.

**Exercise 2.10** An application of the orthogonality relations.

Let $\rho_i$ and $\rho_j$ be irreducible representations of a finite group $G$. Let $\chi_i = \chi_{\rho_i}$ and $\chi_j = \chi_{\rho_j}$. Show that for every $h \in G$,

$$\frac{1}{|G|} \sum_{g \in G} \chi_i(g)\chi_j(g^{-1}h) = \frac{1}{\dim \rho_i} \chi_i(h)\delta_{ij}.$$

**Exercise 2.11** Regular representation of $S_3$.

Decompose the regular representation of $S_3$ into a direct sum of irreducible representations.

Find a basis of each one-dimensional invariant subspace and a projection onto the support of the representation $2\rho$, where $\rho$ is the irreducible representation of dimension 2.

**Exercise 2.12** Real and complexified representations.

Let $E$ be a vector space over $\mathbb{R}$, of dimension $n$. A morphism of a finite group $G$ into $\text{GL}(E)$ is called a real representation of $G$, of (real) dimension $n$.

We consider $E^C = E \oplus iE = E \otimes \mathbb{C}$, a vector space over $\mathbb{C}$, of complex dimension $n$, called the complexification of $E$. 

(a) Show that every real representation of $G$ on $E$ can be extended uniquely to a (complex) representation of $G$ on $E^\mathbb{C}$. This representation is called the complexification of the real representation.

(b) Let the symmetric group $\mathfrak{S}_3$ act on $\mathbb{R}^2$ by rotation through angles of $2k\pi/3$ and reflection. Show that the complexification of this representation is equivalent to the irreducible representation of $\mathfrak{S}_3$ on $\mathbb{C}^2$.

(c) Let the cyclic group of order 3 act on $\mathbb{R}^2$ by rotations through angles of $2k\pi/3$. Is this real representation irreducible?

(d) Are all irreducible real representations of abelian groups one-dimensional?

**Exercise 2.13 Representations of the dihedral group.**

(a) Show that if $H$ is an abelian subgroup of order $p$ of a finite group $G$ of order $n$, then every irreducible representation of $G$ is of dimension $\leq n/p$.

(b) Conclude that for every $n \geq 3$, every irreducible representation of the dihedral group $D_{(n)}$ is one- or two-dimensional.

**Exercise 2.14 Peter–Weyl theorem for finite groups.**

Let $\rho^1, \rho^2, \ldots, \rho^N$ be unitary representations of a finite group $G$, chosen from each equivalence class of irreducible representations.

Show that the matrix coefficients of the representations $\rho^k$, $k = 1, \ldots, N$, in orthonormal bases form an orthogonal basis of $L^2(G)$. Conclude that every function $f \in L^2(G)$ has a “Fourier series”

$$f = \sum_{k=1}^{N} \sum_{i,j=1}^{\dim \rho_k} d_k(\rho^k_{ij}|f) \rho^k_{ij},$$

where the $d_k$ are integers.

**Exercise 2.15 Representation of $\text{GL}(2, \mathbb{C})$ on the polynomials of degree 2.**

Let $G$ be be a group and let $\rho$ be a representation of $G$ on $V = \mathbb{C}^n$. Let $P^{(k)}(V)$ be the vector space of complex polynomials on $V$ that are homogeneous of degree $k$.

(a) For $f \in P^{(k)}(V)$, we set $\rho^{(k)}(g)(f) = f \circ \rho(g^{-1})$. Show that this defines a representation $\rho^{(k)}$ of $G$ on $P^{(k)}(V)$.

(b) Compare $\rho^{(1)}$ and the dual representation of $\rho$.

(c) Suppose that $G = \text{GL}(2, \mathbb{C})$, $V = \mathbb{C}^2$, and $\rho$ is the fundamental representation. Let $k = 2$. To the polynomial $f \in P^{(2)}(\mathbb{C}^2)$ defined by $f(x, y) = ax^2 + 2bxy + cy^2$ we associate the vector $v_f = \begin{pmatrix} a \\ b \\ c \end{pmatrix} \in \mathbb{C}^3$. Let $\tilde{\rho}$ denote the representation of $\text{GL}(2, \mathbb{C})$ on $\mathbb{C}^3$ defined by $\rho^{(2)}$ and the isomorphism above. Find the dual of $\tilde{\rho}$. 
**Exercise 2.16 Convolution.**

Let $G$ be a finite group and let $\mathbb{C}[G]$ be the group algebra of $G$ that is, the vector space $\mathcal{F}(G)$ with multiplication defined by $\epsilon_g \epsilon_{g'} = \epsilon_{gg'}$, for $g$ and $g' \in G$, and extended by linearity.

(a) Show that the product of two functions $f_1, f_2 \in \mathbb{C}[G]$ is the convolution product $(f_1 * f_2)(g) = \sum_{h \in G} f_1(h) f_2(h^{-1} g)$.

(b) Let $\rho$ be a representation of $G$ and suppose $f \in \mathbb{C}[G]$. Set $\rho_f = \sum_{g \in G} f(g) \rho(g)$. Show that $\rho_{f_1 * f_2} = \rho_{f_1} \circ \rho_{f_2}$.

(c) Show that $f \in \mathbb{C}[G]$ is a class function if and only if $f$ is in the center of the algebra $\mathbb{C}[G]$ equipped with convolution (that is, $f$ commutes in the sense of convolution with every function on $G$).

**Exercise 2.17 On the map $f \mapsto \rho_f$.**

For every representation $(E, \rho)$ of $G$ and each function $f$ on $G$, consider the endomorphism $\rho_f$ of $E$ defined by $\rho_f = \sum_{g \in G} f(g) \rho(g)$.

(a) Let $R$ be the regular representation of $G$. Consider $R_f(\epsilon_g)$, for $g \in G$. Show that $R_f(\epsilon_e) = f$. Is the map $f \in \mathbb{C}[G] \mapsto R_f \in \text{End}(\mathbb{C}[G])$ injective?

(b) Let $\rho_i$ and $\rho_j$ be irreducible representations of $G$ and let $\chi_i$ (respectively, $\chi_j$) be the character of $\rho_i$ (respectively, $\rho_j$). Find $\rho_f$ for $\rho = \rho_j$ and $f = \chi_i$.

**Exercise 2.18 Tensor products of representations.**

Let $\rho$ be the irreducible representation of dimension 2 of the symmetric group $\mathfrak{S}_3$. We set $\rho = \rho^{\otimes 1}$, and by induction we define for every integer $k \geq 2$, $\rho^{\otimes k} = \rho^{\otimes (k-1)} \otimes \rho$.

(a) For each positive integer $k$, decompose $\rho^{\otimes k}$ into a direct sum of irreducible representations.

(b) Let $\mathfrak{A}_3 \subset \mathfrak{S}_3$ denote the alternate group. For each positive integer $k$, decompose the restriction of $\rho^{\otimes k}$ to $\mathfrak{A}_3$ into a direct sum of irreducible representations.
Issai Schur, born in 1875 in Mohilev, Belorussia, professor in Bonn and then in Berlin, member of the Prussian Academy of Sciences, lost his university position in 1935. Forced to emigrate to Palestine, he died in Tel Aviv in 1941. Schur is, with Frobenius, a founder of representation theory.

Chapter 3

Representations of Compact Groups

In this chapter, we shall extend to compact topological groups many of the properties proved in the case of finite groups. Some properties will be stated without proof.

1 Compact Groups

Recall that a topological group is a group equipped with the structure of a Hausdorff topological space (for example, a subset of a normed vector space) such that multiplication and inversion are continuous maps. A topological space is locally compact if each point has a compact neighborhood. A topological group that is a compact (respectively, locally compact) space is called a compact group (respectively, locally compact group).

If $E$ is a Banach space (i.e., a complete normed vector space) over the real or complex field, we denote by $\mathcal{L}(E, E)$ the vector space of continuous linear maps of $E$ into $E$ (also called endomorphisms of $E$ or continuous linear operators or bounded operators on $E$). We equip it with the standard norm on linear maps defined, for each continuous, linear $u : E \to E$, by

$$\|u\| = \sup_{\|x\| \leq 1} \|u(x)\|.$$  

For each Banach space $E$ we denote by $\text{GL}(E) \subset \mathcal{L}(E, E)$ the group of isomorphisms of $E$, that is, bijective and bicontinuous endomorphisms of $E$. In order to show that the inverse of a continuous linear operator is continuous, it suffices to show that the operator is bijective. We consider $\text{GL}(E)$ to be a topological subspace of the normed vector space $\mathcal{L}(E, E)$.

The unit ball in a normed vector space is compact if and only if the space is finite-dimensional. Thus each closed and bounded subset of $\text{GL}(E)$, where $E$ is a finite-dimensional vector space, is compact. For example $U(n) \subset \text{GL}(n, \mathbb{C})$ and $O(n) \subset \text{GL}(n, \mathbb{R})$ are compact. Similarly, $\text{SU}(n)$ and $\text{SO}(n)$ are compact. The abelian group $\mathbb{R}$ with its usual metric is locally compact but not compact. The groups $\text{GL}(n, \mathbb{C})$ and $\text{SL}(n, \mathbb{C})$, $\text{GL}(n, \mathbb{R})$, and $\text{SL}(n, \mathbb{R})$ are locally compact but not compact.
2 Haar Measure

On a finite group $G$, we know that for each function $f \in \mathcal{F}(G)$ and for every $g \in G$,
\[ \sum_{h \in G} f(h) = \sum_{h \in G} f(gh) = \sum_{h \in G} f(hg). \]

If we denote by $l_g$ (respectively, $r_g$) the left (respectively, right) multiplication by $g \in G$, we have, by definition, $f(gh) = (f \circ l_g)(h)$ and $f(hg) = (f \circ r_g)(h)$. Consequently, the averaging operation
\[ M : f \mapsto M(f) = \frac{1}{|G|} \sum_{g \in G} f(g) \]
satisfies the following conditions:
- $M$ is a positive linear form on $\mathcal{F}(G)$, that is, $M$ takes nonnegative values on real nonnegative functions;
- $M$ is both left- and right-invariant, that is, $\forall g \in G$, $M(f \circ l_g) = M(f \circ r_g) = M(f)$;
- $M(1) = 1$.

On any compact group there is a measure, the Haar measure, that has analogous properties. More generally, on a locally compact group, there are measures that are either left-invariant or right-invariant but in general, not both.

**Theorem 2.1.** Let $G$ be a locally compact group.

(i) There exists a positive measure on $G$, finite on compact sets and not identically zero, that is left-invariant, i.e., for each integrable function $f$ and for every $h \in G$,
\[ \int_G f(hg) \, d\mu(g) = \int_G f(g) \, d\mu(g). \]

Such a measure is unique up to multiplication by a positive real number. If $f$ is a continuous, nonnegative function, then $\int_G f(g) \, d\mu(g) = 0$ implies $f = 0$.

(ii) If $G$ is compact, there is a unique left-invariant measure $\mu$ such that $\int_G d\mu(g) = 1$.

(iii) On a compact group, every left-invariant measure is right-invariant.

**Proof.** (i) The proof of this result is beyond the scope of this book. See, e.g., Loomis (1953).

(ii) If $\mu_0$ is a left-invariant measure on a compact group $G$ and if $\int_G d\mu_0(g) = m$, we set $\mu = \frac{1}{m} \mu_0$, and $\mu$ is clearly the unique left-invariant measure such that $\int_G d\mu(g) = 1$. 
(iii) Let \( \mu \) be a left-invariant measure on a locally compact group \( G \). For any continuous \( f \) with compact support, we set \( \mu(f) = \int_G f(g) d\mu(g) \). Let \( h \in G \) and consider \( \mu_h(f) = \int_G f(gh) d\mu(g) \), that is, \( \mu_h(f) = \mu(f \circ r_h) \). Then

\[
\forall k \in G, \mu_h(f \circ l_k) = \int_G f(kgh) d\mu(g) = \int_G f(gh) d\mu(g) = \mu_h(f),
\]

and hence, by the uniqueness of left-invariant measures up to a factor, there is a positive real number \( \Delta(h) \) depending on \( h \) satisfying

\[
\mu_h(f) = \Delta(h) \mu(f).
\]

If \( G \) is compact, the constant function 1 is integrable. Therefore we obtain \( \mu_h(1) = \mu(1) = \Delta(h) \mu(1) \). Hence \( \Delta = 1 \), and \( \mu \) is thus also right-invariant, i.e.,

\[
\int_G f(gh) d\mu(g) = \int_G f(g) d\mu(g),
\]

for every \( h \in G \).

\[ \square \]

**Definition 2.2.** On a compact group, the unique left- and right-invariant measure of total mass 1 is called the Haar measure.

On a locally compact group \( G \), the function \( \Delta : h \in G \mapsto \Delta(h) \in \mathbb{R} \) is called the modular function of \( G \). It satisfies

\[
\Delta(hh') = \Delta(h) \Delta(h'),
\]

since \( \Delta(hh') \mu(f) = \mu_{hh'}(f) = \mu(f \circ r_{hh'}) = \mu(f \circ r_{h'} \circ r_h) = \Delta(h) \mu(f \circ r_{h'}) = \Delta(h) \Delta(h') \mu(f) \). We say that a locally compact group \( G \) is unimodular if \( \Delta = 1 \).

The preceding theorem says that if \( G \) is compact, then \( G \) is unimodular.

One often writes \( \int f(g) dg \) instead of \( \int f(g) d\mu(g) \). Thus, if \( G \) is compact, then for each measurable function \( f \),

\[
\forall h \in G, \int_G f(g) dg = \int_G f(hg) dg = \int_G f(gh) dg,
\]

and we require that \( \mu \) satisfy the normalization condition \( \int_G dg = 1 \).

**Examples.**

- On an abelian group, each left-invariant measure is obviously also right-invariant.
- In the case of the locally compact abelian group \( \mathbb{R} \), every invariant measure is proportional to the Lebesgue measure.
- If \( G = U(1) = S^1 = \{ e^{i\theta} | \theta \in \mathbb{R}/2\pi \mathbb{Z} \} = \{ z \in \mathbb{C} \ | \ |z| = 1 \} \), then
  \[
dg = \frac{d\theta}{2\pi} \text{ or } dg = \frac{dz}{2i\pi z}.
\]
- For the groups \( SU(2) \) and \( SO(3) \), see Exercises 5.4, 5.5, and 5.6.
Chapter 3 Representations of Compact Groups

3 Representations of Topological Groups and Schur’s Lemma

All the Hilbert spaces we consider are over the field of complex numbers, and we assume each Hilbert space to be separable, that is, we assume that it has a countable Hilbert space basis.

3.1 General Facts

Definition 3.1. Let $G$ be a topological group. A continuous representation (or simply a representation) of $G$ is defined to be a Hilbert space $E$ and a morphism group $\rho : G \to \text{GL}(E)$ such that for every $x \in E$,

$$g \in G \mapsto \rho(g)x \in E$$

is a continuous mapping.

A sufficient condition for the continuity of the map $g \mapsto \rho(g)x$, for every $x \in E$, is that

$$\lim_{g \to e} \|\rho(g) - \text{Id}_E\| = 0,$$

that is, $\rho$ should be continuous as a map of $G$ into $\text{GL}(E)$ with the topology induced by the norm of $\mathcal{L}(E,E)$. If $E$ is finite-dimensional, this sufficient condition is also necessary.

The dimension, finite or infinite, of $E$ is called the dimension of $\rho$.

The trivial representation of $G$ on a vector space $E$ is defined by $\rho(g) = \text{Id}_E$, for every $g \in G$.

Let $E$ be a complex Hilbert space. If $u \in \mathcal{L}(E,E)$, the adjoint $u^*$ of $u$ is defined by

$$\forall x, y \in E, (ux \mid y) = (x \mid u^*y),$$

and an element $u \in \text{GL}(E)$ is a unitary operator if $uu^* = u^*u = \text{Id}_E$. The group of unitary operators of $E$ is denoted by $U(E)$. In finite dimensions and in an orthonormal basis, a unitary operator is represented by a unitary matrix.

A representation $\rho$ of $G$ on $E$ is called unitary if $E$ is a complex Hilbert space and if for every $g \in G$, $\rho(g)$ is a unitary operator. Then for every $g \in G$, $x, y \in E$, we have $(\rho(g)x \mid \rho(g)y) = (x \mid y)$, and in particular, $\|\rho(g)x\| = \|x\|$. 

Remark. In the same way, one can define representations on real Hilbert spaces. In this case one speaks of orthogonal representations.

3.2 Coefficients of a Representation

Let $E^*$ be the dual of $E$. For $x \in E$ and $\xi \in E^*$, we set

$$\rho_x\xi(g) = \langle \xi, \rho(g)x \rangle,$$
where $\langle \cdot , \cdot \rangle$ denotes the duality pairing. In finite dimensions, given a basis $(e_i)$ of $E$, and the dual basis $(e_i^*)$ in $E^*$, we recover the matrix coefficients $\rho_{ij}$ defined in Chapter 2, because
\[
\rho_{e_j e_i^*}(g) = \langle e_i^*, \rho(g)e_j \rangle = \rho_{ij}(g).
\]
One can also consider, for $x, y \in E$,
\[
\varphi_{xy}^\rho(g) = (x \mid \rho(g)y).
\]
If $\rho$ is unitary, then
\[
\varphi_{xy}^\rho(g^{-1}) = \varphi_{yx}^\rho(g).
\]
In finite dimensions, for each basis $(e_i)$ of $E$, we consider the coefficients
\[
\varphi_{ij}^\rho(g) = (e_i \mid \rho(g)e_j).
\]
If the basis $(e_i)$ is orthonormal, then
\[
\varphi_{ij}^\rho = \rho_{ij}.
\]

### 3.3 Intertwining Operators

**Definition 3.2.** Let $(E_1, \rho_1)$ and $(E_2, \rho_2)$ be unitary representations of $G$. An intertwining operator for $\rho_1$ and $\rho_2$ is defined to be any continuous linear mapping $T : E_1 \to E_2$ such that for every $g \in G$, $\rho_2(g) \circ T = T \circ \rho_1(g)$.

In particular, if $(E, \rho)$ is a unitary representation of $G$, a continuous linear mapping $T : E \to E$ intertwines $\rho$ with itself if and only if it commutes with $\rho$.

Two representations $(E_1, \rho_1)$ and $(E_2, \rho_2)$ are equivalent if there is a bijective (and thus bicontinuous) intertwining operator $T$ for $\rho_1$ and $\rho_2$. Then $E_1$ is isomorphic to $E_2$ and $\rho_2(g) = T \circ \rho_1(g) \circ T^{-1}$. Thus one defines the equivalence class of a representation.

**Definition 3.3.** A representation $(E, \rho)$ of $G$ is called irreducible if $E \neq \{0\}$ and if no closed nontrivial vector subspace of $E$ is invariant under $\rho$.

For a closed vector subspace $F$ invariant under $\rho$, the restriction of $\rho$ to $F$ is called a subrepresentation of $\rho$.

**Proposition 3.4.** If $(E, \rho)$ is a unitary representation and if $F \subseteq E$ is a closed vector subspace invariant under $\rho$, then the orthogonal complement $F^\perp$ of $F$ is also a closed vector subspace invariant under $\rho$, and the orthogonal projections $P_F$ on $F$ and $P_{F^\perp}$ on $F^\perp$ commute with $\rho$.

**Proof.** We know that for every vector subspace $F$ of $E$, the orthogonal complement $F^\perp$ of $F$ is closed. By hypothesis, for every $x \in F$, $\rho(g)x \in F$. Let $y \in F^\perp$. Then for every $x \in F$, $(x \mid y) = 0$. Hence for every $x \in F$, $(x \mid \rho(g)y) = (\rho(g)^{-1}x \mid y) = 0$, and so $\rho(g)y \in F^\perp$. Furthermore,
\[
\rho(g)y = \rho(g)(P_Fy + P_{F^\perp}y) = \rho(g)P_Fy + \rho(g)P_{F^\perp}y.
\]

The first term is $P_F(\rho(g)y)$ and the second is $P_{F^\perp}(\rho(g)y)$.\qed
3.4 Operations on Representations

One can take the Hilbert direct sum \((\oplus E_i, \oplus \rho_i)\) of a countable family of unitary representations \((E_i, \rho_i)\) of a topological group \(G\). In the vector space of the representation, each \(E_i\) is a closed subspace, the \(E_i\) are pairwise orthogonal, and the direct sum is dense.

A representation is called completely reducible (or semisimple) if it is the Hilbert direct sum of irreducible representations.

If \(\rho\) is an irreducible representation, we use the notation \(m\rho\) to denote the isotypic component of type \(\rho\) of a completely reducible representation, where \(m\) can be an integer or \(\infty\).

We define the tensor product \((E_1 \otimes E_2, \rho_1 \otimes \rho_2)\) of two representations \((E_1, \rho_1)\) and \((E_2, \rho_2)\) of \(G\) by setting, for \(g \in G\), \(x_1 \in E_1\), and \(x_2 \in E_2\),
\[
((\rho_1 \otimes \rho_2)(g))(x_1 \otimes x_2) = \rho_1(g)x_1 \otimes \rho_2(g)x_2.
\]
If \(\rho_1\) and \(\rho_2\) are infinite-dimensional representations, we consider \(E_1 \hat{\otimes} E_2\), the tensor product completed under the norm associated to the scalar product defined by
\[
(x_1 \otimes x_2 | x_1' \otimes x_2') = (x_1 | x_1')(x_2 | x_2'),
\]
for \(x_i\) and \(x_i' \in E_i\), \(i = 1, 2\), which can be shown to be positive. The Hilbert space \(E_1 \hat{\otimes} E_2\) is called the Hilbert tensor product of \(E_1\) and \(E_2\).

**Theorem 3.5.** Every finite-dimensional unitary representation of a topological group is completely reducible.

The proof is the same as in the case of finite groups using Proposition 3.4.

There exist (nonunitary) representations that are reducible but not completely reducible.

3.5 Schur’s Lemma

**Theorem 3.6 (Schur’s Lemma).** Let \(G\) be a topological group and let \((E_1, \rho_1)\) and \((E_2, \rho_2)\) be irreducible unitary representations of \(G\). Let \(T\) be a continuous linear mapping of \(E_1\) into \(E_2\) that intertwines \(\rho_1\) and \(\rho_2\). Then either \(T = 0\) or \(T\) is an isomorphism (and consequently \(\rho_1\) and \(\rho_2\) are equivalent), and \(T\) is then unique up to a multiplicative constant.

In summary, if \(\rho_2(g) \circ T = T \circ \rho_1(g)\) for every \(g \in G\), then either \(\rho_1 \sim \rho_2\) and \(T = 0\), or \(\rho_1 \sim \rho_2\) and \(T\) is an isomorphism. The proof, which we omit, uses the spectral decomposition of Hermitian operators. See, e.g., Gurarie(1972).

**Corollary 3.7.** Let \(G\) be a topological group and let \((E, \rho)\) be a unitary representation of \(G\). The representation \(\rho\) is irreducible if and only if every endomorphism of \(E\) that commutes with \(\rho\) is a scalar multiple of the identity.

**Proof.** If \(\rho\) is not irreducible, the projection onto a nontrivial closed invariant subspace is a nonscalar endomorphism of \(E\) that commutes with \(\rho\). The converse is a consequence of Schur’s lemma. \(\square\)
Corollary 3.8. The unitary irreducible representations of an abelian group are one-dimensional.

Proof. Let \((E, \rho)\) be an unitary irreducible representation of an abelian group \(G\). Let \(g\) be an element of \(G\). Then for every \(h \in G\), \(\rho(g)\rho(h) = \rho(h)\rho(g)\), and thus \(\rho(g)\) commutes with \(\rho\). By Corollary 3.7 of Schur’s lemma, \(G\) acts by scalar multiplication. Because the representation \(\rho\) is assumed irreducible, it must be one-dimensional.

\[\square\]

4 Representations of Compact Groups

In this section, we consider a topological group \(G\) that we assume to be compact, and as above, by “representation,” we mean a continuous representation on a separable complex Hilbert space.

4.1 Complete Reducibility

Theorem 4.1. Every representation of a compact group is unitarizable.

Sketch of Proof. Let \(G\) be be a compact group, and let \((E, \rho)\) be a representation of \(G\). We set, for \(x, y \in E\),

\[(x | y)' = \int_G (\rho(g)x | \rho(g)y) dg,\]

where \(dg\) is the Haar measure on \(G\). This is indeed a scalar product because if \((x|x)' = 0\), then by Theorem 2.1, \((\rho(g)x | \rho(g)x) = 0\) for every \(g \in G\), and consequently \(x = 0\). On the other hand,

\[(\rho(g)x | \rho(g)y)' = \int_G (\rho(hg)x | \rho(hg)y) dh = \int_G (\rho(h)x | \rho(h)y) dh = (x | y').\]

Thus \(\rho(g)\) is unitary for \(( | )'\). Next one shows that the norms associated to \(( | )\) and \(( | )'\) are equivalent, which implies that the representation remains continuous and that the representations \(\rho\) on the Hilbert spaces \((E, ( | ))\) and \((E, ( | )')\) are equivalent, which means that the identity mapping of \(E\) is bicontinuous and intertwines the representations.

\[\square\]

Combining this theorem with Theorem 3.5, we obtain the following corollary:

Corollary 4.2. Every finite-dimensional representation of a compact group is completely reducible.

A proof of the following result may be found in, e.g., Naimark–Stern(1982).

Theorem 4.3. Every irreducible representation of a compact group is finite-dimensional.

Remark. This theorem, as specified above, assumes representations to be continuous and representation spaces to be separable complex Hilbert spaces. The theorem is not true in all generality, but it is true for continuous representations taking values in certain topological vector spaces more general than Hilbert spaces.
4.2 Orthogonality Relations

We define a scalar product on the vector space of complex-valued functions on $G$ by

$$(f_1 \mid f_2) = \int_G f_1(g) f_2(g) \, dg,$$

where $dg$ is the haar measure. We denote by $L^2(G)$ the Hilbert space obtained by completing this pre-Hilbert space under the norm defined by the scalar product. This is the Hilbert space of square-integrable function on $G$. (Strictly speaking, this vector space consists of equivalence classes of square-integrable functions under the equivalence relation of equality almost everywhere.)

We know that the irreducible representations of $G$ are finite-dimensional. The orthogonality relations of characters of irreducible representations of finite groups extend to the compact case.

**Theorem 4.4.** Let $G$ be a compact group and let $(E_1, \rho_1)$ and $(E_2, \rho_2)$ be irreducible unitary representations of $G$. For every $x_1, y_1 \in E_1$ and $x_2, y_2 \in E_2$,

$$\langle \varphi_{x_1y_1}^{\rho_1} \mid \varphi_{x_2y_2}^{\rho_2} \rangle \begin{cases} 0 & \text{if } \rho_1 \not\sim \rho_2, \\ \frac{1}{\dim E} (x_2 \mid x_1)(y_1 \mid y_2) & \text{if } E_1 = E_2 = E \text{ and } \rho_1 = \rho_2 = \rho. \end{cases}$$

**Proof.** Generalizing the process used in the proof of Proposition 2.9 of Chapter 2, we define, for each continuous linear mapping $u : E_1 \to E_2$, the following operator intertwining $\rho_1$ and $\rho_2$:

$$T_u = \int_G \rho_2(g) u \rho_1(g)^{-1} \, dg.$$

For $y_1 \in E_1, y_2 \in E_2$, we consider the linear map $u_{y_1y_2} : E_1 \to E_2$ defined by $u_{y_1y_2}(x) = (y_1 \mid x)y_2$, for $x$ in $E_1$. Using the fact that $\rho_1$ is unitary, we then obtain the equation $\langle \varphi_{x_1y_1}^{\rho_1} \mid \varphi_{x_2y_2}^{\rho_2} \rangle = (x_2 \mid T_{u_{y_1y_2}} x_1)$.

Then we apply Schur’s lemma. The quantity above is zero if $\rho_1$ is not equivalent to $\rho_2$. If $E_1 = E_2 = E$ and $\rho_1 = \rho_2 = \rho$, then $T_{u_{y_1y_2}} = \tau(y_1, y_2) \text{Id}_E$, where $\tau(y_1, y_2)$ is antilinear in $x_1$ and linear in $x_2$. We calculate $\tau(y_1, y_2)$ by calculating the trace of $T_{u_{y_1y_2}}$. This is equal to the trace of $u_{y_1y_2}$ because for each linear mapping $u$, $\text{Tr} T_u = \int_G \text{Tr}(\rho(g) \circ u \circ \rho(g^{-1})) \, dg = \int_G \text{Tr} u \, dg = \text{Tr} u$. Because $\text{Tr}(u_{y_1y_2}) = (y_1 \mid y_2)$, we obtain the desired result.

In particular, if $\rho_1$ and $\rho_2$ are inequivalent, then in every orthonormal basis,

$$\langle \varphi_{i j}^{\rho_1} \mid \varphi_{k \ell}^{\rho_2} \rangle = 0,$$

and if $\rho_1 = \rho_2 = \rho$, then

$$\langle \varphi_{i j}^{\rho} \mid \varphi_{k \ell}^{\rho} \rangle = \frac{1}{\dim E} \delta_{ik} \delta_{j \ell}.$$

We denote by $\hat{G}$ the set of equivalence classes of irreducible representations of a compact group $G$. When $L^2(G)$ is separable—which is usually true in the cases one meets in practice—the orthogonality relations above imply that $\hat{G}$ is countable.
By (4.1) and (4.2) the matrix coefficients in orthonormal bases of inequivalent irreducible unitary representations of \( G \) form an orthogonal set in \( L^2(G) \). We now state without proof the Peter–Weyl theorem, which states that these matrix coefficients form an orthogonal basis of \( L^2(G) \) in the Hilbert space sense. For a proof, see, e.g., Simon (1996) or Gurarie(1992).

**Theorem 4.5 (Peter–Weyl Theorem for Compact Groups).** Every function \( f \in L^2(G) \) has a “Fourier series”

\[
f = \sum_{\alpha \in \hat{G}} \sum_{i,j=1} \dim \rho^\alpha c_{ij}^\alpha \rho^\alpha_{ij}
\]

converging in the \( L^2 \) sense, where the \( \rho^\alpha \) are unitary representatives of the classes of inequivalent irreducible representations of \( G \), the \( \rho^\alpha_{ij} \) are their matrix coefficients in orthonormal bases, and

\[
c_{ij}^\alpha = (\dim \rho^\alpha)(\rho^\alpha_{ij} | f) = (\dim \rho^\alpha) \int_G f(g) \overline{\rho^\alpha_{ij}(g)} dg. \tag{4.4}
\]

**Example.** The irreducible representations of the abelian compact group \( G = \mathbb{R}/2\pi \mathbb{Z} \) are the exponentials \( e_k : x \mapsto e^{ikx} \) for \( k \in \mathbb{Z} \). Thus in this case \( \hat{G} = \mathbb{Z} \).

We thus see that the expansion of functions of \( L^2(G) \) as series, where \( G \) is a compact group, given by the Peter–Weyl theorem is a generalization of the Fourier series expansion of 2\( \pi \)-periodic functions square-integrable on \([0, 2\pi]\). If \( G = \mathbb{R}/2\pi \mathbb{Z} \), then for every \( f \in L^2(G) \),

\[
f = \sum_{k \in \mathbb{Z}} c_k e_k, \tag{4.5}
\]

where

\[
c_k = (e_k | f) = \frac{1}{2\pi} \int_0^{2\pi} f(\theta) e^{-ik\theta} d\theta. \tag{4.6}
\]

In this case, each representation is one-dimensional, and its unique matrix coefficient is the character of the representation. The formulas (4.3) and (4.4) are thus seen to be generalizations of the classic formulas (4.5) and (4.6) of Fourier analysis.

If \((E, \rho)\) is a finite-dimensional representation of \( G \), we define the **character** \( \chi_\rho \) of \( \rho \) by

\[
\forall g \in G, \ \chi_\rho(g) = \text{Tr}(\rho(g)).
\]

The complex-valued function thus defined on \( G \) is continuous. It is a class function that depends only on the equivalence class of the representation \( \rho \).

**Theorem 4.6 (Orthogonality Relations).** Let \( \rho_1 \) and \( \rho_2 \) be irreducible representations of \( G \). Then

\[
(\chi_{\rho_1} | \chi_{\rho_2}) = \begin{cases} 
0 & \text{if } \rho_1 \sim \rho_2, \\
1 & \text{if } \rho_1 \sim \rho_2.
\end{cases}
\]
Proof. With the help of Theorem 4.1, these relations are a consequence of the preceding formulas (4.1) and (4.2).

A representation $\rho$ is irreducible if and only if $(\chi_\rho | \chi_\rho) = 1$.

If $\rho$ is a representation of $G$, we can decompose it as a Hilbert sum of irreducible representations $\rho_i$, where $i \in \hat{G}$. We shall write

$$\rho = \bigoplus_{i \in \hat{G}} m_i \rho_i,$$

where

$$m_i = (\chi_{\rho_i} | \chi_\rho).$$

We may have $m_i = \infty$.

Theorem 4.1 of Chapter 2 concerning the projection operators generalizes as follows. A projection on the isotypic component $m_i \rho_i$ is

$$P_i = \text{dim} \rho_i \int_G \overline{\chi_i(g)} \rho(g)dg.$$

In general, many results from the representation theory of finite groups extend to the case of compact groups, replacing averaging over the group with the Haar integral.

We shall determine the irreducible representations of the compact groups SU(2) and SO(3) in Chapter 6.

The following section summarizes the principal properties of the representations of compact groups, compared to those of finite groups.

5 Summary of Chapter 3

We summarize the properties of finite groups that are true also for compact groups. The representations are assumed continuous on separable complex Hilbert spaces.

The matrix coefficients in orthonormal bases of unitary irreducible representations form an orthogonal basis of the vector space $L^2(G)$ as an orthogonal set.

Every representation has a decomposition into a direct Hilbert sum

$$\rho = \bigoplus_{i=1}^{\infty} m_i \rho_i$$

$$m_i = \langle \chi_i | \chi_\rho \rangle$$

Decomposition of the regular representation

$$\sum_{i=1}^{N}(\dim \rho_i)^2 = |G|$$

Each irreducible representation is contained in the regular representation a number of times equal to its dimension true

Projection onto an isotypic component

$$P_i = \frac{\dim \rho_i}{|G|} \sum_{g \in G} \overline{\chi_i(g)} \rho(g)$$

$$P_i = \dim \rho_i \int_G \overline{\chi_i(g)} \rho(g) dg$$

For a proof of the bicontinuity of continuous bijective operators, as well as other results in analysis, see Rudin (1991) or Brezis (1983).

See Gurarie (1972) for a thorough introductory text, including a proof of Schur’s lemma (Theorem 3.6), and Naimark–Štern (1982) for a comprehensive study of irreducible representations on Hilbert spaces, including a proof of Theorem 4.3. For a generalization to locally convex topological vector spaces, see Kirillov (1976).

The Peter–Weyl theorem is proved in most of the books mentioned. It was published in 1926 by Hermann Weyl and one of his students, Fritz Peter (1899–1949), who became headmaster of a secondary school.
Exercises

Exercise 3.1 Continuity condition for a representation

Let $E$ be a Hilbert space and let $\rho$ be a morphism of the locally compact group $G$ into $\text{GL}(E)$, the group of bijective continuous linear operators from $E$ to $E$. (One knows that such an operator is bicontinuous.) We consider the following conditions:

(i) $\rho$ is a continuous mapping of $G$ into $\text{GL}(E)$ with the usual norm.
(ii) $\lim_{g \to e} \|\rho(g) - id_E\| = 0$.
(iii) The mapping $(g, x) \in G \times E \mapsto \rho(g)(x) \in E$ is continuous.
(iv) For each $x \in E$, the mapping $g \in G \mapsto \rho(g)(x) \in E$ is continuous (in which case $\rho$ is called a representation of $G$ on $E$).

(a) Show that conditions (i) and (ii) are equivalent.
(b) Show that (i) implies (iii).
(c) Show that the conditions (iii) and (iv) are equivalent. [We know by the Banach–Steinhaus theorem (uniform boundedness theorem) that if $K$ is a compact subset of $G$ and if $\sup_{g \in K} \|\rho(g)(x)\| < \infty$, for every $x \in E$, then $\sup_{g \in K} \|\rho(g)\| < \infty$.]
(d) Show that if $E$ is finite-dimensional, these conditions are equivalent.

Exercise 3.2 Dual of a unitary representation.

Show that the dual representation of a unitary representation of a compact group is equivalent to the conjugate representation.

Exercise 3.3 Regular representation of a compact group.

Let $G$ be a compact group, and let $E = L^2(G)$ be the Hilbert space of square-integrable functions on $G$ with respect to the Haar measure. We set, for every $f \in L^2(G), g, h \in G$.

$$(R(g)(f))(h) = f(g^{-1}h).$$

Show that $R$ is a unitary representation of $G$ on $L^2(G)$.

Exercise 3.4 Equivalence of representations.

Show that two equivalent unitary representations of a topological group are unitarily equivalent. [Hint: Introduce the adjoint $T^*$ of the intertwining operator $T$ and the positive square root of the positive self-adjoint operator $TT^*$.]

Exercise 3.5 An application of Schur’s lemma.

Let $(E, \rho)$ be an irreducible representation of a compact group $G$. Show that if two scalar products on $E$ are invariant under the representation $\rho$, they are proportional.
Exercise 3.6 A not completely reducible representation.

Let $G$ be the group of complex matrices $( \begin{pmatrix} a & b \\ 0 & 1 \end{pmatrix} )$ such that $|a| = 1$, with the usual topology.

(a) Is this group compact?
(b) Show that the fundamental representation of $G$ on $\mathbb{C}^2$ is reducible, but not completely reducible.
(c) Find the endomorphisms of $\mathbb{C}^2$ that commute with the fundamental representation of $G$.

Exercise 3.7 Haar measure.

(a) Find the Haar measure on $O(2)$.
(b) Find the left-invariant and the right-invariant measures on the group of affine transformations of $\mathbb{R}$.

Exercise 3.8 Representations of the direct product of two compact groups.

Let $(E_1, \rho_1)$ and $(E_2, \rho_2)$ be finite-dimensional representations of compact groups $G_1$ and $G_2$, respectively. Show that we can define a representation $\rho = \rho_1 \times \rho_2$ of $G_1 \times G_2$ on $E_1 \otimes E_2$ by $\rho(g_1, g_2)(v_1 \otimes v_2) = \rho_1(g_1)v_1 \otimes \rho_2(g_2)v_2$, for $g_1 \in G_1, g_2 \in G_2, v_1 \in E_1, v_2 \in E_2$. Show that each irreducible representation of $G_1 \times G_2$ is of the form $(E_1 \otimes E_2, \rho_1 \times \rho_2)$, where $(E_i, \rho_i)$ is an irreducible representation of $G_i$, $i = 1, 2$. 
Arthur Tresse (1868–1958), a student of Lie, submitted his thesis in 1893 in Paris. It was published in Acta Mathematica, 18 (1893), pp. 1–88. In the introduction, page 3, he gives the groups studied by Lie the name “groupes de Lie”: “then I recall the general propositions of Mr. Lie concerning the groups that are defined by systems of partial differential equations, groups which I shall call Lie groups.”
Chapter 4

Lie Groups and Lie Algebras

We restrict ourselves to the study of linear Lie groups, that is, to closed subgroups of GL\((n, \mathbb{R})\), for an integer \(n\), in other words, to groups of real matrices. We adopt the convention, introduced in Chapter 1, of calling such a group simply a Lie group. We shall show that to each Lie group there corresponds a Lie algebra. For ease of exposition, we start by defining Lie algebras, and return later to the study of groups.

1 Lie Algebras

1.1 Definition and Examples

We can define Lie algebras over any field. We restrict ourselves to the real or complex case. So let \(K = \mathbb{R}\) or \(\mathbb{C}\).

**Definition 1.1.** A Lie algebra \(\mathfrak{a}\) over \(K\) is a finite- or infinite-dimensional \(K\)-vector space with a \(K\)-bilinear, antisymmetric operation \([ , ]\) satisfying the Jacobi identity

\[
\forall X, Y, Z \in \mathfrak{a}, \ [X, [Y, Z]] + [Y, [Z, X]] + [Z, [X, Y]] = 0. \tag{1.1}
\]

The bilinear operation \([ , ]\) is called the Lie bracket (or simply bracket).

**Examples.**

- The vector space \(\mathbb{R}^3\) with the cross product is a real Lie algebra of dimension 3.
- Let \(E\) be a \(K\)-vector space. We define the commutator of two \(K\)-linear operators \(u\) and \(v\) on \(E\) by

\[
[u, v] = u \circ v - v \circ u. \tag{1.2}
\]

The verification of the Jacobi identity is immediate, because

\[
u \circ (v \circ w - w \circ v) - (v \circ w - w \circ v) \circ u + v \circ (w \circ u - u \circ w) - (w \circ u - u \circ w) \circ v + w \circ (u \circ v - v \circ u) - (u \circ v - v \circ u) \circ w = 0.
\]
Thus the commutator defines a Lie algebra structure on the vector space of $\mathbb{K}$-linear operators on $E$.

In particular, the vector space of $n \times n$ matrices with coefficients in the field $\mathbb{K}$, with the commutator

$$[X, Y] = XY - YX,$$

is a Lie algebra over $\mathbb{K}$ of dimension $n^2$, denoted by $\mathfrak{gl}(n, \mathbb{K})$.

**Definition 1.2.** A **Lie subalgebra** of a Lie algebra is a vector subspace closed under the bracket.

Thus each $\mathbb{K}$-vector subspace of $\mathfrak{gl}(n, \mathbb{K})$ closed under the commutator is a Lie algebra on $\mathbb{K}$.

**Examples.**

- The vector space of real (respectively, complex) matrices of trace zero is a real (respectively, complex) Lie algebra.
- The vector space of complex anti-Hermitian matrices is a real Lie algebra.
- The vector space of real antisymmetric matrices is a real Lie algebra.
- More generally, if $p + q = n$, we denote by $J_{pq}$ the diagonal matrix with $p$ diagonal elements 1 followed by $q$ diagonal elements $-1$, and we set

$$\mathfrak{so}(p, q) = \{ X \in \mathfrak{gl}(n, \mathbb{R}) \mid XJ_{pq} + J_{pq}^t X = 0 \}.$$  

This is a Lie subalgebra of $\mathfrak{gl}(n, \mathbb{R})$. In fact, for $X$ and $Y \in \mathfrak{so}(p, q)$,

$$J_{pq}(t^t X - ^t X t^t Y) = -YJ_{pq}^t X + XJ_{pq}^t Y = -(XY - YX)J_{pq}.$$

**Remark.** Neither the vector space of symmetric matrices nor that of Hermitian matrices is stable under the commutator.

A Lie algebra is called **abelian** if the bracket is identically zero.

An **ideal** of $\mathfrak{a}$ is a Lie subalgebra $\mathfrak{b}$ of $\mathfrak{a}$ such that $[\mathfrak{a}, \mathfrak{b}] \subset \mathfrak{b}$, i.e., for every element $X$ in $\mathfrak{a}$ and for every element $Y$ in $\mathfrak{b}$, $[X, Y]$ is in $\mathfrak{b}$. In any Lie algebra $\mathfrak{a}$, the ideals $\{0\}$ and $\mathfrak{a}$ itself are called the **trivial ideals**.

The **center** of a Lie algebra $\mathfrak{a}$ is the abelian ideal of $\mathfrak{a}$,

$$\{ X \in \mathfrak{a} \mid \forall Y \in \mathfrak{a}, [X, Y] = 0 \}.$$  

A Lie algebra is called **simple** if it has no nontrivial ideals and is not of dimension 0 or 1. It is called **semisimple** if it has no nonzero abelian ideals.

If $E$ is a normed vector space over $\mathbb{K}$, we consider the vector space of continuous $\mathbb{K}$-linear maps of $E$ into $E$, with the standard norm of linear maps satisfying the inequality

$$\|u \circ v\| \leq \|u\|\|v\|.$$  

This vector space with the commutator (1.2) is a Lie subalgebra of the Lie algebra of all linear operators on $E$. We denote it by $\mathfrak{gl}(E)$.

If $E$ is finite-dimensional, every linear map on $E$ is continuous; therefore in this case $\mathfrak{gl}(E)$ is the Lie algebra of all linear operators on $E$. In particular, $\mathfrak{gl}(\mathbb{K}^n)$ can be identified with the Lie algebra $\mathfrak{gl}(n, \mathbb{K})$ of $n \times n$ matrices with coefficients in $\mathbb{K}$. 
1.2 Morphisms

Let \( a \) and \( b \) be Lie algebras over \( K \). A **morphism** of Lie algebras of \( a \) into \( b \) is a \( K \)-linear map \( \varphi \) of \( a \) into \( b \) such that

\[
\forall X,Y \in a, [\varphi X, \varphi Y]_b = \varphi([X,Y]_a).
\]

An **isomorphism** of \( a \) onto \( b \) is a bijective morphism. An **automorphism** of \( a \) is an isomorphism of \( a \) onto \( a \). We write \( \text{Aut}(a) \) for the group of automorphisms of \( a \).

For all of the following, we shall consider **finite-dimensional** Lie algebras.

1.3 Commutation Relations and Structure Constants

Let \( a \) be a Lie algebra of finite dimension \( d \), and let \( (e_i) \), \( i = 1, \ldots, d \), be a basis of the vector space \( a \). The **commutation relations** of \( a \) in the basis \( (e_i) \) are the Lie brackets \( [e_i, e_j] \), \( 1 \leq i < j \leq d \). The constants, real or complex numbers \( C_{ij}^k \) such that

\[
[e_i, e_j] = \sum_{k=1}^d C_{ij}^k e_k,
\]

are called **structure constants**. If two finite-dimensional Lie algebras have the same commutation relations, they are isomorphic. More precisely, if there exist in the Lie algebras \( a \) and \( b \) of the same finite dimension bases \( (e_i) \) and \( (f_i) \) such that the structure constants are the same, then the linear isomorphism of \( a \) onto \( b \) defined by \( e_i \mapsto f_i \) is an isomorphism of Lie algebras.

1.4 Real Forms

On the one hand, each complex vector space \( E \) can be considered as a vector space over \( \mathbb{R} \), denoted by \( E^\mathbb{R} \), of twice the dimension. On the other hand, each real vector space \( E \) can be complexified by setting \( E^\mathbb{C} = E \oplus iE = E \otimes \mathbb{C} \) and by setting \( i(X + iY) = -Y + iX \), for every \( X \) and \( Y \) \( \in E \). Note that if \( E \) is a complex (respectively, real) vector space and \( E \neq \{0\} \), then \( (E^\mathbb{R})^\mathbb{C} \neq E \) (respectively, \( (E^\mathbb{C})^\mathbb{R} \neq E \)), as one can easily see by calculating the dimensions.

If \( a \) is a complex Lie algebra, we denote by \( a^\mathbb{R} \) the Lie algebra over \( \mathbb{R} \) (of twice the dimension) obtained by “realification.” On the other hand, if \( a \) is a real Lie algebra, the corresponding complexified vector space can be given the structure of a complex Lie algebra by setting \( [X,iY] = i[X,Y] \) and \( [iX,iY] = -[X,Y] \), for every \( X \) and \( Y \) \( \in a \). We denote by \( a^\mathbb{C} \) the complex Lie algebra thus obtained, called the **complexification** of the real Lie algebra \( a \).

A **real form** of a complex Lie algebra \( g \) is a real Lie algebra \( a \) such that \( a^\mathbb{C} = g \). For example, \( (\mathfrak{gl}(n,\mathbb{R}))^\mathbb{C} = \mathfrak{gl}(n,\mathbb{C}) \). In general, a complex Lie algebra has several nonisomorphic real forms.
1.5 Representations of Lie Algebras

Here we define Lie algebra representations, restricting ourselves to the case of finite-dimensional representations. We shall see in Section 7.2 the relationship between representations of groups and representations of Lie algebras.

Definition 1.3. Let $\mathfrak{g}$ be a Lie algebra over $\mathbb{K}$. A representation of $\mathfrak{g}$ is a $\mathbb{K}$-linear mapping $R$ of $\mathfrak{g}$ into $\mathfrak{gl}(E)$, where $E$ is a finite-dimensional complex vector space satisfying

$$\forall X, Y \in \mathfrak{g}, \ [R(X), R(Y)] = R([X, Y]).$$

A representation of a complex Lie algebra $\mathfrak{g}$ on a complex vector space $E$ is thus a morphism of complex Lie algebras of $\mathfrak{g}$ into $\mathfrak{gl}(E)$. The dimension of $E$ is called the dimension of the representation.

A representation of a real Lie algebra $\mathfrak{g}$ on a complex vector space $E$ is a morphism of real Lie algebras of $\mathfrak{g}$ into $\mathfrak{gl}(E)^{\mathbb{R}}$. We show below (Proposition 1.4) that such a morphism has a unique extension to a morphism of complex Lie algebras of $\mathfrak{g}^{\mathbb{C}}$ into $\mathfrak{gl}(E)$. Later, we study numerous examples. Here is a very simple one. The matrices

$$\eta_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{pmatrix}, \quad \eta_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{pmatrix}, \quad \eta_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}$$

form a basis of a real Lie algebra $\mathfrak{g} = \mathfrak{so}(3)$, of dimension 3, whose commutation relations are

$$[\eta_k, \eta_\ell] = \eta_m$$

for each cyclic permutation $k, \ell, m$ of 1, 2, 3. To the elements $\eta_1, \eta_2, \eta_3$ of $\mathfrak{g}$ we associate the complex $2 \times 2$ matrices

$$\xi_1 = \frac{i}{2} \sigma_1, \quad \xi_2 = -\frac{i}{2} \sigma_2, \quad \xi_3 = \frac{i}{2} \sigma_3,$$

where

$$\sigma_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},$$

are the Pauli matrices. Because

$$[\xi_k, \xi_\ell] = \xi_m,$$

we see immediately that the $\mathbb{R}$-linear map of $\mathfrak{so}(3)$ into $\mathfrak{gl}(2, \mathbb{C})^{\mathbb{R}}$ defined by $\eta_k \mapsto \xi_k$ is a representation of $\mathfrak{g}$ on $\mathbb{C}^2$. Furthermore, extending this map by $\mathbb{C}$-linearity defines a morphism of complex Lie algebras of $\mathfrak{so}(3)^{\mathbb{C}}$ into $\mathfrak{gl}(2, \mathbb{C})$.

Remark. We can also define the real representations of Lie algebras over $\mathbb{K}$, which are $\mathbb{R}$-linear maps into $\mathfrak{gl}(E)$, where $E$ is a real vector space.

A representation $(E, R)$ of $\mathfrak{g}$ is called irreducible if $E \neq \{0\}$ and there are no nontrivial subspaces of $E$ invariant under $R$, i.e., the only vector subspaces of $E$ invariant under $R$ are $\{0\}$ and $E$ itself.
Representations \((E_1, R_1)\) and \((E_2, R_2)\) of a Lie algebra \(g\) are equivalent if there is an isomorphism \(T\) of \(E_1\) onto \(E_2\) such that
\[
\forall X \in g, \ R_2(X) \circ T = T \circ R_1(X).
\]

**Proposition 1.4.** Let \(g^C\) be the complexification of a real Lie algebra \(g\). Every representation of \(g\) can be extended uniquely to a representation of \(g^C\). There is a bijective correspondence between irreducible representations of \(g\) and of \(g^C\).

**Proof.** Let \((E, R)\) be a representation of the Lie algebra \(g\) on a complex vector space \(E\). We set
\[
\forall X, Y \in g, \ R(X + iY) = R(X) + iR(Y) \in \text{gl}(E).
\]
A calculation using the equation
\[
R([X, X']) = R(X) \circ R(X') - R(X') \circ R(X),
\]
for \(X, X' \in g\), shows that
\[
R([X + iY, X' + iY']) = R(X + iY) \circ R(X' + iY') - R(X' + iY') \circ R(X + iY).
\]
Thus the extension of \(R\) is a representation of \(g^C\). The uniqueness is obvious. On the other hand, from a representation of \(g^C\) one can define a representation of \(g\) by restriction. Thus it is clear that there is a bijective correspondence between representations of \(g\) and representations of \(g^C\). Furthermore, if a representation of \(g\) is irreducible, the corresponding representation of \(g^C\) is irreducible as well.

In summary, the equivalence relation on the representations of \(g\) corresponds to the equivalence relation on the representations of \(g^C\). Thus the equivalence classes of irreducible representations of \(g\) and of \(g^C\) are in bijective correspondence.

### 2 Review of the Exponential Map

Let \(X \in \text{gl}(n, \mathbb{R})\). We set
\[
\exp X = e^X = \sum_{p=0}^{\infty} \frac{X^p}{p!}.
\]
For each compact set \(K \subset \text{gl}(n, \mathbb{R})\) there exists a positive real number \(M\) such that \(\|X\| \leq M\) for all \(X \in K\). Therefore when we equip \(\text{gl}(n, \mathbb{R})\) with the standard norm of linear maps, which satisfies the inequality (1.4), the series (2.1) is convergent and uniformly convergent on each compact set.

We have
\[
\exp 0 = I, \quad (2.2)
\]
\[
\forall s, t \in \mathbb{R}, \ \exp(sX) \exp(tX) = \exp(s + t)X. \quad (2.3)
\]
Furthermore, if \(XY = YX\) (but in this case only!), then \(\exp(X + Y) = \exp X \exp Y\).
We deduce from (2.3) that for every $X$, $\exp X$ is invertible with inverse $(\exp X)^{-1} = \exp(-X)$.

Thus the exponential map is a map from $\mathfrak{gl}(n, \mathbb{K})$ into the group of invertible matrices $\text{GL}(n, \mathbb{K}) \subset \mathfrak{gl}(n, \mathbb{K})$.

**Lemma 2.1.** The map $t \in \mathbb{R} \mapsto \exp(tX) \in \text{GL}(n, \mathbb{K})$ is differentiable and

$$\frac{d}{dt} \exp(tX) = X \exp(tX) = \exp(tX)X.$$  

(2.4)

**Proof.** The term-by-term differentiation of the exponential series for $\exp(tX)$ is legitimate and gives

$$\frac{d}{dt} \sum_{p=0}^{\infty} \frac{X^p}{p!} t^p = \sum_{p=1}^{\infty} X^p \frac{t^{p-1}}{(p-1)!} = X \sum_{p=0}^{\infty} \frac{X^p t^p}{p!} = X \exp(tX) = \exp(tX)X,$$

for every $t \in \mathbb{R}$. \hfill \square

In particular,

$$\frac{d}{dt} \exp(tX) \big|_{t=0} = X.$$  

(2.5)

**Proposition 2.2.** The exponential map of $\mathfrak{gl}(n, \mathbb{K})$ into $\text{GL}(n, \mathbb{K}) \subset \mathfrak{gl}(n, \mathbb{K})$ is smooth, and its differential at the origin is the identity map of $\mathfrak{gl}(n, \mathbb{K})$ into itself.

**Proof.** We have

$$\exp X = I + X + X \sum_{p=2}^{\infty} \frac{X^{p-1}}{p!},$$

whence $\|\exp X - \exp 0 - X\| \leq \|X\| \varepsilon(X)$, where

$$\varepsilon(X) = \left\| \sum_{p=2}^{\infty} \frac{X^{p-1}}{p!} \right\| \leq \|X\| \left\| \sum_{q=0}^{\infty} \frac{X^q}{(q+2)!} \right\|.$$

This last series converges, so $\lim_{\|X\| \to 0} \|\varepsilon(X)\| = 0$, which shows that $\exp$ is differentiable at 0, with differential $\text{Id}_{\mathfrak{gl}(n, \mathbb{K})}$.

One can show that the map $\exp$ is differentiable at each point and is of class $C^{\infty}$ (see Exercise 4.6), and we shall use this result. \hfill \square

By the inverse function theorem, we obtain the following result.

**Corollary 2.3.** There exist an open neighborhood $U_0$ of 0 in $\mathfrak{gl}(n, \mathbb{K})$ and an open neighborhood $V_0$ of $I$ in $\text{GL}(n, \mathbb{K})$ such that $\exp$ is a diffeomorphism of $U_0$ onto $V_0$. 
We call the inverse diffeomorphism, defined on a neighborhood of $I \in \text{GL}(n, \mathbb{K})$, the \textit{logarithm}. We denote it by $\log$ (or sometimes $\ln$). Then,

$$\forall X \in \mathfrak{gl}(n, \mathbb{K}) \text{ such that } \|X\| < 1, \quad \log(I + X) = \sum_{p=0}^{\infty} (-1)^p \frac{X^{p+1}}{p + 1}.$$  

**Proposition 2.4.** For every $X, Y \in \mathfrak{gl}(n, \mathbb{K})$,

$$\exp(tX) \exp(tY) = \exp \left( t(X + Y) + \frac{t^2}{2} [X, Y] + O(t^3) \right). \quad (2.6)$$

**Proof.** For $t$ near 0, on the one hand,

$$\exp(tX) \exp(tY) = \left( I + tX + \frac{t^2}{2} X^2 + O(t^3) \right) \left( I + tY + \frac{t^2}{2} Y^2 + O(t^3) \right)$$

$$= I + t(X + Y) + \frac{t^2}{2} (X^2 + 2XY + Y^2) + O(t^3).$$

On the other hand,

$$\exp \left( t(X + Y) + \frac{t^2}{2} (XY - YX) + O(t^3) \right)$$

$$= I + t(X + Y) + \frac{t^2}{2} (XY - YX) + \frac{t^2}{2} (X^2 + XY + YX + Y^2) + O(t^3).$$

The two expressions are thus equal. \hfill \square

One could expand further and consider the coefficients of the terms of order $t^3, t^4$, etc. The result is known as the Baker–Campbell–Hausdorff formula.

**Corollary 2.5.** The exponential of a sum can be expressed as

$$\exp(X + Y) = \lim_{k \to +\infty} \left( \exp \frac{X}{k} \exp \frac{Y}{k} \right)^k. \quad (2.7)$$

**Proof.** We have, for every positive integer $k$,

$$\left( \exp \frac{X}{k} \exp \frac{Y}{k} \right)^k = \left( \exp \left( \frac{1}{k} (X + Y) + O \left( \frac{1}{k^2} \right) \right) \right)^k$$

$$= \exp \left( X + Y + O \left( \frac{1}{k} \right) \right),$$

so the result follows by the continuity of the exponential map. \hfill \square

**Proposition 2.6.** For each $X \in \mathfrak{gl}(n, \mathbb{K})$,

$$\exp(\text{Tr}X) = \det(\exp X). \quad (2.8)$$

In particular, the exponential of a traceless matrix is a matrix of determinant 1.
Proof. Over $\mathbb{C}$, one can triangularize the matrix $X$. If $X$ is similar to a triangular matrix $T$, then $\exp X$ is similar to $\exp T$. If the diagonal coefficients of $T$ are $a_1, \ldots, a_n$, then the diagonal coefficients of the matrix $\exp T$ are $e^{a_1}, \ldots, e^{a_n}$. Hence
\[
\det(\exp X) = \prod_{i=1}^{n} e^{a_i} = e^{\sum_{i=1}^{n} a_i} = e^{\text{Tr} X}.
\]
Over $\mathbb{R}$, the equation is valid for real numbers. \hfill \square

**Corollary 2.7.** We have
\[
\frac{d}{dt} \left. \det(\exp(tX)) \right|_{t=0} = \text{Tr} X.
\]

**Proof.** In formula (2.8), we replace $X$ by $tX$ and differentiate. \hfill \square

### 3 One-Parameter Subgroups of $\text{GL}(n, \mathbb{K})$

We shall show that in the case of one-parameter subgroups of the group of invertible matrices, the hypothesis of continuity implies differentiability.

**Definition 3.1.** A one-parameter subgroup of a topological group $G$ is a continuous map $f : \mathbb{R} \to G$ such that
\[
\forall t \in \mathbb{R}, \forall s \in \mathbb{R}, f(t + s) = f(t)f(s).
\]

We may also simply write one-parameter group. The definition implies that $f(0) = e$.

**Lemma 3.2.** Let $f : \mathbb{R} \to \text{GL}(n, \mathbb{K})$ be a one-parameter subgroup of $\text{GL}(n, \mathbb{K})$. Then $f$ is differentiable.

**Proof.** Let $a \in \mathbb{R}$, $a > 0$. The map $f$ is continuous, and thus $\int_{0}^{a} f(t)dt$ exists. For each $s \in \mathbb{R},$
\[
\int_{0}^{a} f(t + s)dt = f(s) \int_{0}^{a} f(t)dt = \int_{s}^{s+a} f(t)dt.
\]
This quantity is differentiable with respect to $s$. To prove that $f$ is differentiable, it is sufficient to show that there is a real number $a > 0$ such that $\int_{0}^{a} f(t)dt$ is invertible. Now, because $f$ is continuous at 0 and $f(0) = I$,
\[
\exists a > 0, \ |t| \leq a, \ \|f(t) - I\| \leq \frac{1}{2},
\]
whence we deduce that
\[
\left\| \frac{1}{a} \left( \int_{0}^{a} f(t)dt \right) - I \right\| = \left\| \frac{1}{a} \int_{0}^{a} (f(t) - I)dt \right\| \leq \frac{1}{2} < 1,
\]
and thus $\int_{0}^{a} f(t)dt$ is invertible. \hfill \square
Proposition 3.3. Let \( f : \mathbb{R} \to \text{GL}(n, \mathbb{K}) \) be a one-parameter subgroup of \( \text{GL}(n, \mathbb{K}) \). There exists a unique \( X \in \mathfrak{gl}(n, \mathbb{K}) \) such that for each \( t \in \mathbb{R} \),

\[
f(t) = \exp(tX).
\] (3.1)

Proof. The uniqueness is clear, since \( f \) is differentiable by the preceding lemma, and hence the desired matrix \( X \) must satisfy the equation

\[
\frac{d}{dt} f(t) \bigg|_{t=0} = X.
\] (3.2)

We have

\[
\frac{d}{dt} f(t) = \lim_{s \to 0} \frac{f(t + s) - f(t)}{s} = \lim_{s \to 0} f(t) \frac{f(s) - f(0)}{s} = f(t) X.
\]

By Lemma 2.1, we see that \( f(t) \) and \( \exp(tX) \) are solutions of the same differential equation with the same initial condition \( f(0) = I \). The proposition follows. \( \square \)

Definition 3.4. The element \( X \) of \( \mathfrak{gl}(n, \mathbb{K}) \) satisfying (3.1) is called the infinitesimal generator of the one-parameter group \( t \mapsto f(t) \).

We have

\[
X = f'(0)
\]

and, more generally,

\[
\forall t \in \mathbb{R}, \ (f(t))^{-1} f'(t) = X.
\] (3.3)

Example. The rotations around the axes 0x, 0y, 0z, respectively, constitute the one-parameter groups

\[
\begin{pmatrix}
1 & 0 & 0 \\
0 & \cos t & -\sin t \\
0 & \sin t & \cos t
\end{pmatrix}, \quad
\begin{pmatrix}
\cos t & 0 & \sin t \\
0 & 1 & 0 \\
-\sin t & 0 & \cos t
\end{pmatrix}, \quad
\begin{pmatrix}
\cos t & -\sin t & 0 \\
\sin t & \cos t & 0 \\
0 & 0 & 1
\end{pmatrix},
\]

of the form \( \exp(t\eta_i) \), \( i = 1, 2, 3 \), where the infinitesimal generators are the matrices \( \eta_1, \eta_2, \eta_3 \) defined in Section 1.5.

Important Remark. In physics, the name “infinitesimal generator” of a one-parameter group \( f(t) \) is given to the matrix \( A \) satisfying

\[
f(t) = \exp(-itA).
\]

Thus \( A = iX \). In particular, if the one-parameter group consists of unitary transformations of a finite-dimensional Hilbert space, then the operator \( A \) is Hermitian (self-adjoint), and the operator \( X \) is anti-Hermitian. In infinite dimensions, the problem is that the operator \( A \) is not necessarily bounded.
4 Lie Groups

**Definition 4.1.** A linear Lie group is a closed subgroup of a group $GL(n, \mathbb{K})$.

We can identify $GL(m, \mathbb{C})$ with a closed subgroup of $GL(2m, \mathbb{R})$. In fact, each complex $m \times m$ matrix $A$ can be written $A = B + iC$, where $B$ and $C$ are real $m \times m$ matrices and the $\mathbb{R}$-linear map $A \mapsto \begin{pmatrix} B & -C \\ C & B \end{pmatrix}$ of $GL(m, \mathbb{C})$ onto a closed subgroup of $GL(2m, \mathbb{R})$ is a morphism of groups. A linear Lie group is thus a closed subgroup of $GL(n, \mathbb{R})$, for a certain $n$. In Chapter 1 we have given an abstract definition of real Lie groups as smooth manifolds equipped with a group structure compatible with their differentiable structure, and we have stated that each linear Lie group is a real Lie group. In the following, we study only linear Lie groups, and by convention, we call them simply Lie groups. There exist Lie groups that are not linear Lie groups, such as the universal cover of $SL(2, \mathbb{R})$. Most of the properties proved below extend to the general case.

In Chapter 1, we saw several examples of Lie groups: the real and complex special linear groups in dimension $n$, the orthogonal groups, and the unitary groups, related by

$$
SO(n) \subset O(n) \subset GL(n, \mathbb{R}) \quad \text{and} \quad SU(n) \subset U(n) \subset GL(n, \mathbb{C}) \quad \text{with} \quad SU(n) \subset SL(n, \mathbb{C}) \cap SL(n, \mathbb{R})
$$

For each positive integer $n$, the additive group $\mathbb{R}^n$ is isomorphic to the group of $(n + 1) \times (n + 1)$ matrices of the form $\begin{pmatrix} I_x & 0 \\ 0 & 1 \end{pmatrix}$, where $x \in \mathbb{R}^n$, or to the group of matrices $\begin{pmatrix} e^{x_1} & & \\ & \ddots & \\ & & e^{x_n} \end{pmatrix}$, and is thus a Lie group.

The group of affine transformations of $\mathbb{R}^n$ is a Lie group.

The symplectic groups $Sp(n, \mathbb{C})$ and $Sp(n)$ are defined by

$$
Sp(n, \mathbb{C}) = \{ A \in SL(2n, \mathbb{C}) \mid AJ^tA = J \},
$$

$$
Sp(n) = Sp(n, \mathbb{C}) \cap U(2n),
$$

where $J = \begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}$, and are Lie groups.

5 The Lie Algebra of a Lie Group

Let $G$ be a Lie group, i.e., a closed subgroup of $GL(n, \mathbb{R})$. We consider

$$
\mathfrak{g} = \{ X = \gamma'(0) \mid \gamma : I \to G, \ \text{of class} \ C^1, \ \gamma(0) = I \},
$$

where $I$ is an open interval of $\mathbb{R}$ containing 0. This is the set of vectors tangent to parametrized curves of class $C^1$ in $G$ passing through $I$ for the value 0 of the parameter. We shall show that $\mathfrak{g}$ is not only a real vector space, but also a Lie subalgebra of $gl(n, \mathbb{R})$. 
Theorem 5.1. Let $G$ be a Lie group and let $\mathfrak{g}$ be defined as above.

(i) $\mathfrak{g}$ is a vector subspace of $\mathfrak{gl}(n, \mathbb{R})$.
(ii) $X \in \mathfrak{g}$ if and only if for every $t \in \mathbb{R}$, $\exp(tX) \in G$.
(iii) If $X \in \mathfrak{g}$ and if $g \in G$, then $gXg^{-1} \in \mathfrak{g}$.
(iv) $\mathfrak{g}$ is closed under the matrix commutator.

Proof. (i) Let $\gamma : I \to G$ be of class $C^1$ and such that $\gamma(0) = I$. Set $\gamma'(0) = X$.

For each $\lambda \in \mathbb{R}$, the parametrized curve $t \mapsto \gamma(\lambda t)$ has tangent vector $\lambda X$ at $0$.

Thus $\mathfrak{g}$ is closed under multiplication by real scalars. Let $\gamma_i : I \to G$, $i = 1, 2$, be of class $C^1$ and such that $\gamma_i(0) = I$.

Let $X_1 = \gamma_1'(0)$, $X_2 = \gamma_2'(0)$. Then

$$\frac{d}{dt} (\gamma_1(t)\gamma_2(t)) |_{t=0} = X_1 + X_2.$$

Thus $\mathfrak{g}$ is closed under addition.

(ii) It is clear that if $\exp(tX) \in G$, then $X = \frac{d}{dt} \exp(tX)|_{t=0} \in \mathfrak{g}$.

Conversely, if $X \in \mathfrak{g}$, then by hypothesis, $X = \frac{d}{dt} \gamma(t)|_{t=0}$, with $\gamma(t) \in G$.

By the Taylor expansion, for any positive integer $k$, 

$$\gamma \left( \frac{t}{k} \right) = I + \frac{t}{k} X + O \left( \frac{1}{k^2} \right) = \exp \left( \frac{t}{k} X + O \left( \frac{1}{k^2} \right) \right).$$

We can deduce that

$$\left( \gamma \left( \frac{t}{k} \right) \right)^k = \exp \left( tX + O \left( \frac{1}{k} \right) \right),$$

and hence

$$\lim_{k \to +\infty} \left( \gamma \left( \frac{t}{k} \right) \right)^k = \exp(tX).$$

This equation implies that $\exp(tX) \in G$ because $\gamma(\frac{1}{k}) \in G$, and $G$ is a closed subgroup.

(iii) If $X \in \mathfrak{g}$ and $g \in G$, then $gXg^{-1} = \frac{d}{dt} \exp(t(gXg^{-1}))|_{t=0}$, and for every $t$, the matrix $\exp(t(gXg^{-1})) = g(\exp(tX))g^{-1}$ belongs to $G$, so $gXg^{-1} \in \mathfrak{g}$.

(iv) Let $X$ and $Y \in \mathfrak{g}$. Then, $\exp(tX) \in G$ and $\exp(tX)Y \exp(-tX) \in \mathfrak{g}$, by (iii). In the vector space $\mathfrak{g}$, we consider

$$\frac{d}{dt} (\exp(tX)Y \exp(-tX)) |_{t=0}.$$

This element of $\mathfrak{g}$ is $XY - YX = [X,Y]$. □

Definition 5.2. The Lie algebra $\mathfrak{g}$, the tangent space to $G$ at $I$, is called the Lie algebra of the Lie group $G$.

Property (ii) of Theorem 5.1 is the fundamental characterization of the Lie algebra of a Lie group.

The dimension of the real vector space $\mathfrak{g}$ is called the dimension of the Lie group $G$. This is the number of independent parameters necessary to
parametrize the points of the group. (This is also the dimension of the Lie group as a real manifold.)

If the group $G$ is a discrete subgroup of $\text{GL}(n, \mathbb{R})$, a continuous curve in $G$ is necessarily constant, and the Lie algebra of the group is thus reduced to $\{0\}$, and the dimension of the group is 0.

Examples. The Lie algebras of $\text{GL}(n, \mathbb{K}), \text{SL}(n, \mathbb{K}), \text{O}(n), \text{SO}(n), \text{U}(n), \text{SU}(n)$ are denoted respectively by $\mathfrak{gl}(n, \mathbb{K}), \mathfrak{sl}(n, \mathbb{K}), \mathfrak{o}(n), \mathfrak{so}(n), \mathfrak{u}(n), \mathfrak{su}(n)$. The notation $\mathfrak{gl}(n, \mathbb{K})$ is consistent with our previous notation: it is the vector space of all the $n \times n$ matrices with coefficients in $\mathbb{K}$ equipped with the commutator.

Proposition 5.3. The Lie algebras of $\text{SL}(n, \mathbb{K}), \text{O}(n), \text{SO}(n), \text{U}(n)$, and $\text{SU}(n)$ are

- $\mathfrak{sl}(n, \mathbb{K}) = \{X \in \mathfrak{gl}(n, \mathbb{K}) \mid \text{Tr } X = 0\}$ is the Lie algebra of traceless $n \times n$ matrices with coefficients in $\mathbb{K}$, and $\dim_{\mathbb{R}} \mathfrak{sl}(n, \mathbb{K}) = n^2 - 1$, $\dim_{\mathbb{C}} \mathfrak{sl}(n, \mathbb{C}) = n^2 - 1$, $\dim_{\mathbb{R}} \mathfrak{sl}(n, \mathbb{C}) = 2(n^2 - 1)$.

- $\mathfrak{o}(n) = \mathfrak{so}(n) = \{X \in \mathfrak{gl}(n, \mathbb{R}) \mid X + ^t X = 0\}$ is the Lie algebra of antisymmetric real $n \times n$ matrices and $\dim \mathfrak{so}(n) = n(n - 1)/2$.

- $\mathfrak{u}(n) = \{X \in \mathfrak{gl}(n, \mathbb{C}) \mid X + ^t X = 0\}$ is the Lie algebra of anti-Hermitian complex $n \times n$ matrices and $\dim \mathfrak{u}(n) = n^2$.

- $\mathfrak{su}(n) = \{X \in \mathfrak{gl}(n, \mathbb{C}) \mid X + ^t X = 0, \text{Tr} X = 0\}$ is the Lie algebra of traceless anti-Hermitian complex $n \times n$ matrices and $\dim_{\mathbb{R}} \mathfrak{su}(n) = n^2 - 1$.

Proof. In each case we express the condition for $\exp(tX)$ to belong to the indicated Lie group, for every $t \in \mathbb{R}$. \hfill \Box

In certain, but not all, cases, where the Lie group $G$ is a subgroup of $\text{GL}(n, \mathbb{C})$, its Lie algebra has the structure of a complex vector space. This is the case for $\mathfrak{sl}(n, \mathbb{C})$, but not for $\mathfrak{u}(n)$.

Theorem 5.4. The application $\exp$ is a diffeomorphism of a neighborhood of 0 in $\mathfrak{g}$ onto a neighborhood of 0 in $\text{I}$ in $G$.

Proof. Let $U_0$ be a neighborhood of 0 in $\mathfrak{gl}(n, \mathbb{R})$ and let $V_0$ be a neighborhood of $I$ in $\text{GL}(n, \mathbb{R})$ such that $\exp$ is a diffeomorphism of $U_0$ onto $V_0$, as in Corollary 2.3. We consider a supplementary vector subspace $\mathfrak{g}'$ of $\mathfrak{g}$ in $\mathfrak{gl}(n, \mathbb{R})$.

We shall first show by contradiction that there exists a neighborhood $U'_0 \subset U_0$ of 0 in $\mathfrak{g}'$ such that the two conditions $X \in U'_0$ and $\exp X \in G$ imply $X = 0$. Suppose then that in each neighborhood of 0 in $\mathfrak{g}'$ there is an $X \neq 0$ such that $\exp X \in G$. In particular, for every $n$, there is an $X_n \in \frac{1}{n}(U_0 \cap \mathfrak{g}')$, $X_n \neq 0$, such that $\exp X_n \in G$. Thus we construct a sequence $(X_n)$ in $\mathfrak{g}'$ that tends to 0 as $n$ tends to infinity. We set $Y_n = X_n/\|X_n\|$, which implies $\|Y_n\| = 1$. Because the unit sphere is compact, there is a subsequence of $(Y_n)$ that converges in the vector space $\mathfrak{g}'$ to a limit $Y$ of norm 1. For $t \in \mathbb{R}$, we consider the integral part $p_n(t)$ of $t/\|X_n\|$ defined by

$$
\frac{t}{\|X_n\|} = p_n(t) + u_n(t), \quad p_n(t) \in \mathbb{Z}, \quad u_n(t) \in [0, 1].
$$
The connected component of the identity 59

Then

$$\exp \left( \frac{t}{\|X_n\|} X_n \right) = (\exp X_n)^{p_n(t)} \exp(u_n(t)X_n).$$

The sequence $\exp(u_n(t)X_n)$ tends to $I$, since the sequence $(u_n(t))$ is bounded and the sequence $(X_n)$ tends to 0, and $(\exp X_n)^{p_n(t)}$ is in $G$ since $G$ is a group. Therefore the sequence $\exp \left( \frac{t}{\|X_n\|} X_n \right)$ tends to an element in $G$. Because the exponential map is continuous, the limit of $\exp \left( \frac{t}{\|X_n\|} X_n \right)$ is $\exp(tY)$, which is therefore in $G$. By Theorem 5.1 (ii), this in turn implies that $Y$ is in $g$, which contradicts the hypothesis $g \cap g' = \{0\}$.

Now let $\alpha : g \oplus g' \to GL(n, \mathbb{R})$ be the map defined by

$$\alpha(X, X') = \exp X \exp X'.$$

The differential at 0 of $\alpha$ is the identity, and thus $\alpha$ is a local diffeomorphism of a product $U \times U'$ of neighborhoods of 0 in $g$ and $g'$ respectively onto a neighborhood $W$ of $I$ in $GL(n, \mathbb{R})$. We can assume that $U' \subseteq U'_0$. We show that $W \cap G = \exp U$. It is clear that $\exp U \subseteq W \cap G$. On the other hand, if $g \in W \cap G$, then $g = \exp X \exp X'$, where $X \in U \subseteq g$, $X' \in U'_0 \subseteq g'$. Then we have $X' = 0$, since $X' \in U'_0$ and $\exp X' = (\exp X)^{-1} g \in G$. Thus $W \cap G \subseteq \exp U$. \hfill \Box

6 The Connected Component of the Identity

Definition 6.1. The connected component of a point $g \in G$ is the largest connected set contained in $G$ and containing $g$. The connected component of the identity is often called the connected component of $G$ for short. We shall denote it by $G_0$.

The connected component of a point $g \in G$ is the union of the connected sets contained in $G$ and containing $g$. Clearly, if $G$ is connected, $G = G_0$ and $G$ has only one component.

Proposition 6.2. Each connected component of $G$ is open and closed in $G$.

Proof. Each connected component is closed because the closure of a connected set is connected. It is also open. In fact, each point of $G$ has a connected neighborhood: for $I$, the image of a ball centered at the origin under the exponential map; for an arbitrary element of the group, the translate of such a neighborhood. For $h$ in the connected component of $g \in G$, let $V$ be a connected neighborhood of $h$. Then $V$ is contained in the connected component of $g$, and thus the connected component of $g$ is a neighborhood of $h$. \hfill \Box

Recall that the only nonempty open subset of a connected set is the set itself. It follows that $G$ is the disjoint union of its connected components.

Proposition 6.3. The connected component of the identity of $G$ is a subgroup of $G$. Any open and closed subgroup of $G$ contains the connected component of the identity of $G$. 

Chapter 4 Lie Groups and Lie Algebras

Proof. If \( g \in G_0 \), the left translate of \( G_0 \) by \( g^{-1} \) is diffeomorphic to \( G_0 \), and thus is connected, and it contains \( I \), so it is contained in \( G_0 \). Thus, \( G_0 \) is a subset containing \( I \) and such that for every \( g \) and \( g' \in G_0 \), \( g^{-1}g' \) is in \( G_0 \), i.e., \( G_0 \) is a subgroup.

Let \( H \) be an open and closed subgroup of \( G \). Then \( H \cap G_0 \) is open and closed. Since it contains \( I \), it is nonempty. Therefore \( H \cap G_0 = G_0 \). \( \square \)

Example. The connected component of \( O(n) \) is \( SO(n) \). For \( n = 3 \), this fact will be proved in Section 2.1 of Chapter 5.

Proposition 6.4. Every neighborhood of the identity in \( G \) generates a subgroup of \( G \) containing the connected component of the identity. In particular, if the Lie group \( G \) is connected, every neighborhood of the identity generates \( G \).

Proof. Let \( U \) be an open neighborhood of \( I \) in \( G \), and let \( H \) be the subgroup generated by \( U \). Because the translations are diffeomorphisms, for every \( g \in H \), the subset \( Ug \) of \( H \) is open, and it is contained in \( H \) because \( H \) is a subgroup of \( G \). Thus \( H \) is open. On the other hand, each open subgroup \( H \) of any topological group is also closed. In fact, the entire group is the union of left (or right) cosets modulo \( H \) and each class is open. Since \( H \) is the complement of the union of cosets other than that of the identity, and since this union of open sets is open, we deduce that \( H \) is closed. Thus the subgroup \( H \) is open and closed. We deduce that it contains the connected component of the identity. \( \square \)

Theorem 6.5. Let \( G \) be be a Lie group and let \( \mathfrak{g} \) be its Lie algebra. The subgroup of \( G \) generated by \( \exp \mathfrak{g} \) is the connected component of the identity. In particular, if \( G \) is connected, each element of \( G \) is the product of a finite number of exponentials.

Proof. By Theorem 5.4, the image of the exponential map is a neighborhood of the identity. Thus the subgroup that it generates contains \( G_0 \), by Proposition 6.4. Because \( \exp \mathfrak{g} \) is connected, it is contained in \( G_0 \) and so is the subgroup that it generates, since \( G_0 \) is a subgroup of \( G \), by Proposition 6.3. Therefore \( \exp \mathfrak{g} \) generates \( G_0 \). \( \square \)

Every \( g \in G_0 \) is thus a finite product \( \exp X_1 \cdots \exp X_k \), \( X_i \in \mathfrak{g} \).

7 Morphisms of Lie Groups and of Lie Algebras

We defined in Section 1.2 the algebraic notion of a morphism of Lie algebras. Now we define the morphisms of Lie groups and consider the close relationship between these two definitions.

7.1 Differential of a Lie Group Morphism

Definition 7.1. Let \( G \) and \( G' \) be Lie groups. A morphism of Lie groups, or Lie group morphism, \( f : G \to G' \) is a continuous morphism of groups of \( G \) into \( G' \). Most authors use the term homomorphism.
Theorem 7.2. Let $f$ be a Lie group morphism of $G$ into $G'$, and let $\mathfrak{g}$ and $\mathfrak{g}'$ be the Lie algebras of $G$ and $G'$, respectively.

(i) For each $X \in \mathfrak{g}$, the map $t \in \mathbb{R} \mapsto f(\exp(tX)) \in G'$ is a one-parameter subgroup of $G'$.

(ii) Let

$$\varphi(X) = \frac{d}{dt}f(\exp(tX))|_{t=0}. \quad (7.1)$$

Then for every $t \in \mathbb{R}$,

$$f(\exp(tX)) = \exp(t\varphi(X)), \quad (7.2)$$

and in particular,

$$f(\exp X) = \exp(\varphi(X)). \quad (7.3)$$

(iii) The map $\varphi : X \mapsto \varphi(X)$ is a morphism of Lie algebras from $\mathfrak{g}$ into $\mathfrak{g}'$.

Proof. (i) The map $t \mapsto f(\exp(tX))$ is continuous and also satisfies the group property

$$f(\exp((t+s)X)) = f(\exp(tX) \exp(sX)) = f(\exp(tX)) f(\exp(sX)).$$

It is therefore a one-parameter subgroup of $G'$, and by Lemma 3.2, we can differentiate the map $t \mapsto f(\exp(tX))$.

(ii) Because $\varphi(X) = \frac{d}{dt}f(\exp(tX))|_{t=0}$ is the infinitesimal generator of the one-parameter group $t \mapsto f(\exp(tX))$, we obtain (7.2) and in particular, (7.3).

$$f(\exp X) = \exp(\varphi(X)). \quad (7.4)$$

(iii) Let us show that $\varphi$ is $\mathbb{R}$-linear. Let $s$ be a real number. Then $\varphi(sX) = s\varphi(X)$. In fact, $t \mapsto f(\exp(t(sX)))$ is a one-parameter subgroup with infinitesimal generator

$$\frac{d}{dt}f(\exp(tsX))|_{t=0} = s \frac{d}{du}f(\exp(uX))|_{u=0} = s\varphi(X).$$

Now this infinitesimal generator is $\varphi(sX)$ by definition. Thus $\varphi(sX) = s\varphi(X)$.

Let us show that $\varphi$ is additive. Let $X$ and $Y$ be elements of $\mathfrak{g}$. On the one hand, the map $t \mapsto f(\exp(t(X+Y)))$ is a one-parameter subgroup of $G'$, with infinitesimal generator $\varphi(X+Y)$. On the other hand, using Corollary 2.5 and the continuity of $f$, we obtain

$$\exp(t\varphi(X+Y)) = f(\exp(t(X+Y))) = \lim_{k \to +\infty} f\left(\left(\exp\left(\frac{t}{k}X\right) \exp\left(\frac{t}{k}Y\right)\right)^k\right)$$

$$= \lim_{k \to +\infty} \left(f\left(\exp\left(\frac{t}{k}X\right)\right) f\left(\exp\left(\frac{t}{k}Y\right)\right)^k\right)$$

$$= \lim_{k \to +\infty} \left(\exp\left(\frac{t}{k}\varphi(X)\right) \exp\left(\frac{t}{k}\varphi(Y)\right)^k\right).$$
because \( \frac{1}{k} \varphi(X) \) is the infinitesimal generator of \( t \mapsto f(\exp(\frac{t}{k}X)) \). Thus
\[
\exp(t\varphi(X + Y)) = \exp(t(\varphi(X) + \varphi(Y))).
\]
Hence
\[
\varphi(X + Y) = \varphi(X) + \varphi(Y).
\]

It remains to show that \( \varphi \) preserves the commutator. Let us show first that
\[
\forall g \in G, \forall X \in \mathfrak{g}, \varphi(gXg^{-1}) = f(g)\varphi(X)(f(g))^{-1}.
\]
In fact,
\[
\exp(t\varphi(gXg^{-1})) = f(\exp(g(tX)g^{-1})) = f(g \exp(tX)g^{-1})
\]
\[
= f(g)f(\exp(tX))f(g^{-1}) = f(g)\exp(t\varphi(X)) (f(g))^{-1}
\]
\[
= \exp(tf(g)\varphi(X)f(g^{-1}))
\]
whence for every \( Y \in \mathfrak{g} \) and for every \( t \in \mathbb{R} \),
\[
\varphi(\exp(tY)X \exp(-tY)) = f(\exp(tY))\varphi(X)f(\exp(-tY)).
\]
Differentiating at 0, since the map \( \varphi \) is linear, we obtain
\[
\varphi(YX - XY) = \varphi(Y)\varphi(X) - \varphi(X)\varphi(Y),
\]
which is the desired equation. \( \Box \)

**Definition 7.3.** The morphism of Lie algebras \( \varphi \) defined by (7.1) is called the differential of the Lie group morphism \( f \), and is denoted by \( Df \).

Thus, by definition,
\[
(Df)(X) = \left. \frac{d}{dt} f(\exp(tX)) \right|_{t=0}.
\]

**Remark.** A Lie group, more generally a topological space, is called simply connected if each continuous loop can be deformed continuously to a point. If the Lie group \( G \) is connected and simply connected, then for every morphism of real Lie algebras \( \varphi \) of \( \mathfrak{g} \) into \( \mathfrak{g}' \), there is conversely a unique Lie group morphism of \( G \) into \( G' \) whose differential is \( \varphi \). For a proof of this important theorem, see, e.g., Rossmann (2002) or Hall (2003).

### 7.2 Differential of a Lie Group Representation

One may define and study the infinite-dimensional representations of Lie groups. In particular, if the Lie group is compact, the results of Chapter 3 concerning the representations on separable complex Hilbert spaces apply. But we shall nonetheless limit ourselves here to the case of finite-dimensional representations. If \( E \) is a finite-dimensional complex vector space, then \( \text{GL}(E) \) is a (real) Lie group, with Lie algebra \( \mathfrak{gl}(E)^{\mathbb{R}} \).
Definition 7.4. A representation of a Lie group $G$ is a Lie group morphism from $G$ into $\text{GL}(E)$, where $E$ is a finite-dimensional complex vector space.

Let $\rho$ be a representation of a Lie group $G$ on a finite-dimensional complex vector space $E$. We denote by $D\rho$ the differential of the Lie group morphism $\rho : G \to \text{GL}(E)$. This is a morphism of Lie algebras of $\mathfrak{g}$ into $\mathfrak{gl}(E)_{\mathbb{R}}$ (and in particular into $\mathfrak{gl}(n,\mathbb{C})_{\mathbb{R}}$ if $E = \mathbb{C}^n$). Thus $D\rho$ is a representation of the Lie algebra $\mathfrak{g}$ on $E$ in the sense of Definition 1.3. We have, by definition, for each $X \in \mathfrak{g}$,

$$
(D\rho)(X) = \frac{d}{dt} \rho(\exp(tX)) \bigg|_{t=0}.
$$

(7.6)

In other words, $\rho(\exp(tX))$ is a one-parameter subgroup of $\text{GL}(E)$ with infinitesimal generator $(D\rho)(X)$, and we then have, for every $t \in \mathbb{R}$,

$$
\rho(\exp(tX)) = \exp(t(D\rho)(X)).
$$

(7.7)

The following definition is thus justified.

Definition 7.5. Let $(E, \rho)$ be a representation of a Lie group $G$. The differential of the representation $\rho$ is the Lie algebra representation $D\rho : \mathfrak{g} \to \mathfrak{gl}(E)$ defined by (7.5).

Theorem 7.6. Let $(E, \rho)$ be a representation of a Lie group $G$.

(i) If $F \subset E$ is invariant under $\rho$, then $F$ is invariant under $D\rho$.

(ii) If $D\rho$ is irreducible, then $\rho$ is irreducible.

(iii) If $(E, (\ | \ ))$ is a finite-dimensional complex Hilbert space and if $(E, \rho)$ is unitary, then the Lie algebra representation $(E, D\rho)$ is anti-Hermitian.

(iv) Let $(E_1, \rho_1)$ and $(E_2, \rho_2)$ be representations of $G$. If $\rho_1 \sim \rho_2$, then $D\rho_1 \sim D\rho_2$.

The converses are true if $G$ is connected.

Proof. (i) If for every $X \in \mathfrak{g}$ and for every $t \in \mathbb{R}$, $F$ is invariant under $\rho(\exp(tX))$, then $F$ is invariant under $(D\rho)(X)$.

(ii) is an immediate consequence of (i).

(iii) Suppose $\rho$ is unitary. Then for every $X \in \mathfrak{g}$ and every $t \in \mathbb{R}$,

$$
(\rho(\exp(tX))u \mid \rho(\exp(tX))v) = (u \mid v),
$$

for every $u$ and $v \in E$. Differentiating with respect to $t$ at $t = 0$, we obtain

$$
(D\rho(X)u \mid v) + (u \mid D\rho(X)v) = 0,
$$

(7.8)

which says that $D\rho$ is anti-Hermitian.

(iv) If there exists a bijective linear map $T : E_1 \to E_2$ satisfying

$$
\forall g \in G, \rho_2(g) \circ T = T \circ \rho_1(g),
$$

$$

\right
then by setting \( g = \exp(tX) \) and differentiating with respect to \( t \), we obtain the desired equation

\[
\forall X \in \mathfrak{g}, \quad (D\rho_2)(X) \circ T = T \circ (D\rho_1)(X).
\]

The converses are true if \( G \) is connected because, in this case, every element of \( G \) is the product of a finite number of exponentials, by Theorem 6.5. We prove, for example, the converse of (iii). Suppose \( D\rho \) is anti-Hermitian. Using the equation

\[
\frac{d}{dt} \rho(\exp tX) = D\rho(X) \circ \rho(\exp tX),
\]

we obtain

\[
\frac{d}{dt} (\rho(\exp tX)u | \rho(\exp tX)v) = (D\rho(X)\rho(\exp tX)u | \rho(\exp tX)v) + (\rho(\exp tX)u | D\rho(X)\rho(\exp tX)v).
\]

This quantity is zero for every \( t \in \mathbb{R} \) by hypothesis. Thus the value of the scalar product \( (\rho(\exp tX)u | \rho(\exp tX)v) \) remains constant and equal to the value \( (u | v) \) it takes at \( t = 0 \). Thus \( \rho \) is unitary. \( \square \)

If \((E_1, \rho_1)\) and \((E_2, \rho_2)\) are representations of \( G \), then

\[
D(\rho_1 \oplus \rho_2) = D\rho_1 \oplus D\rho_2
\]

and

\[
D(\rho_1 \otimes \rho_2) = D\rho_1 \otimes \text{Id}_{E_2} + \text{Id}_{E_1} \otimes D\rho_2,
\]

that is, explicitly, for every \( X \in \mathfrak{g} \) and for every \( v_1 \in E_1, v_2 \in E_2 \),

\[
D(\rho_1 \otimes \rho_2)(X)(v_1 \otimes v_2) = (D\rho_1)(X)v_1 \otimes v_2 + v_1 \otimes (D\rho_2)(X)v_2.
\]

This equation is proved by taking the derivative at \( t = 0 \) of the equation defining \( \rho_1 \otimes \rho_2 \),

\[
(\rho_1 \otimes \rho_2)(g)(v_1 \otimes v_2) = \rho_1(g)v_1 \otimes \rho_2(g)v_2,
\]

for \( g \in G \) and \( v_1 \in E_1, v_2 \in E_2 \), where \( g = \exp(tX) \).

### 7.3 The Adjoint Representation

Let \( G \) be be a Lie group with Lie algebra \( \mathfrak{g} \). We consider the conjugation action of \( G \) on itself. For each \( g \in G \),

\[
\mathcal{C}_g : h \in G \mapsto ghg^{-1} \in G
\]

is an automorphism of the Lie group \( G \) that leaves the identity element of \( G \) invariant. The differential of \( \mathcal{C}_g \) at the identity is a linear mapping of \( \mathfrak{g} \) into \( \mathfrak{g} \), called the adjoint action of \( g \) and denoted by \( \text{Ad}_g \). From the equation \( \mathcal{C}_{gg'} = \mathcal{C}_g \circ \mathcal{C}_{g'} \), for \( g \) and \( g' \in G \), we see that

\[
\text{Ad}_{gg'} = \text{Ad}_g \circ \text{Ad}_{g'}.
\]

Furthermore, because \( \text{Ad}_g \) is the identity of \( \mathfrak{g} \) when \( g = I \), we deduce that \( \text{Ad} : g \in G \mapsto \text{Ad}_g \in \text{GL}(\mathfrak{g}) \) is a representation of \( G \) on \( \mathfrak{g} \).
**Definition 7.7.** The representation $\text{Ad}$ of $G$ on $\mathfrak{g}$ is called the adjoint representation of the Lie group $G$.

To the representation $\text{Ad}$ of the Lie group $G$ on $\mathfrak{g}$ there corresponds a representation $D(\text{Ad})$ of the Lie algebra $\mathfrak{g}$ on itself, called the adjoint representation of the Lie algebra $\mathfrak{g}$, and denoted by ad. The following equation is thus true by definition, for every $t \in \mathbb{R}$ and each $X \in \mathfrak{g}$:

$$\text{Ad}_{\exp(tX)} = \exp(t\text{ad}X).$$

(7.11)

**Proposition 7.8.** (i) Let $A$ be an invertible matrix belonging to the Lie group $G$ and let $X$ be a matrix belonging to the Lie algebra $\mathfrak{g}$ of $G$. Then

$$\text{Ad}_A(X) = AXA^{-1}.$$ 

(ii) Let $X$ and $Y \in \mathfrak{g}$. Then

$$\text{ad}_X(Y) = [X,Y].$$

(iii) Let $X$ and $Y \in \mathfrak{g}$. Then

$$\text{ad}_{[X,Y]} = [\text{ad}_X, \text{ad}_Y].$$

(7.12)

**Proof.** (i) By definition, for $B \in G$, we have $\mathcal{C}_A(B) = ABA^{-1}$, and thus

$$\text{Ad}_A(X) = \frac{d}{dt} A \exp(tX) A^{-1} \bigg|_{t=0} = AXA^{-1}.$$

(ii) Furthermore,

$$\text{ad}_X(Y) = \frac{d}{dt} \text{Ad}_{\exp(tX)}(Y) \bigg|_{t=0} = \frac{d}{dt} \exp(tX) Y \exp(-tX) \bigg|_{t=0} = XY - YX = [X,Y].$$

(iii) Equation (7.12) expresses the fact that ad is a Lie algebra representation. It is a direct consequence of the Jacobi identity. \qed

**References**

Most of the results of this chapter extend beyond the case of linear Lie groups to the case of Lie groups in general. Rossmann (2002) first treats the linear Lie groups and then introduces the general notion of Lie groups. In this spirit, one could also consult the books of Hall (2003) and of Baker (2002), while Sagle and Walde (1973), Postnikov (1986), Marsden and Ratiu (1999), Sattinger and Weaver (1993), Kirillov (2008) treat the general case. See Gilmore (1974) for many examples and applications to physics.

There are numerous more advanced textbooks, such as Bump (2004) and Godement (2004). The most classical book still available is Chevalley (1946). For the study of the differential geometry of Lie groups as manifolds, see

For the theorem on the integration of a morphism of Lie algebras to a morphism of Lie groups in the simply connected case mentioned in Section 7.1, see Hall (2003), Naimark–Štern (1982), or Rossmann (2002).

Exercises

Exercise 4.1 The exponential mapping and Lie brackets.
Let \( X \) and \( Y \) be real or complex \( n \times n \) matrices. Show that for \( t, s \in \mathbb{R}, k \in \mathbb{N}^* \),

(a) \( \exp(tX) \exp(tY) \exp(-tX) = \exp(tY + t^2 [X,Y] + O(t^3)) \).
(b) \( \exp(tX) \exp(tY) \exp(-tX) \exp(-tY) = \exp(t^2 [X,Y] + O(t^3)) \).
(c) \( \exp t[X,Y] = \lim_{k \to +\infty} (\exp(\frac{X}{k}) \exp(\frac{Y}{k}) \exp(-\frac{X}{k}) \exp(-\frac{Y}{k}))^k \).
(d) \( [X,Y] = \frac{\partial^2}{\partial t \partial s} (\exp(tX) \exp(sY) \exp(-tX) \exp(-sY)) \bigg|_{t=s=0} \).

Exercise 4.2 Infinite-dimensional Lie algebra: vector fields on \( \mathbb{R}^n \).
Consider the vector space of first-order linear differential operators on \( \mathbb{R}^n \), of the form \( D = \sum_{i=1}^n X^i \frac{\partial}{\partial x^i} \), where each \( X^i \) is a smooth function on \( \mathbb{R}^n \).
Show that the commutator gives this vector space the structure of an infinite-dimensional Lie algebra over \( \mathbb{R} \).

Exercise 4.3 Infinite-dimensional Lie algebra: vector fields on the circle (the Virasoro algebra).
Consider the vector space \( E \) of smooth maps from the circle \( S^1 = \{e^{i\theta} | 0 \leq \theta < 2\pi\} \) into \( \mathbb{C} \) and set, for \( f, g \in E \), \( X_f = f(\theta) \frac{d}{d\theta} \).

(a) Let \( f, g \in E \). Show that there exists \( h \in E \) such that \( [X_f, X_g] = X_h \).
Conclude that \( E \) is a Lie algebra, whose Lie bracket we denote as usual by \( [\ , \] \). Calculate \( [e^{ni\theta}, e^{mi\theta}] \), for \( n, m \in \mathbb{Z} \). This Lie algebra is called the Witt algebra.

(b) Set
\( c(f, g) = \int_0^{2\pi} f(\theta) \frac{d^3 g}{d\theta^3} d\theta \).
Let \( \tilde{E} = E \oplus \mathbb{C} \), and let \( k \) be a complex constant. For every \( (f, \lambda) \) and \( (g, \mu) \in \tilde{E} \), set
\( [(f, \lambda), (g, \mu)]_k = ([f, g], k \cdot c(f, g)) \).
Show that \( (\tilde{E}, [\ , \])_k \) is a Lie algebra. Calculate \( [(e^{ni\theta}, \lambda), (e^{mi\theta}, \mu)]_k \), for \( n, m \in \mathbb{Z} \). This Lie algebra is called the Virasoro algebra.
Exercise 4.4 Example of a nonsurjective exponential map.

(a) Show that the exponential map of $\mathfrak{sl}(2, \mathbb{C})$ into $\text{SL}(2, \mathbb{C})$ is not surjective.
(b) Is the exponential map always injective?

Exercise 4.5 The Heisenberg group.

(a) Let
\[
X = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad Y = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad H = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.
\]
Calculate $[H, X]$, $[H, Y]$ and $[X, Y]$. Calculate $\exp(tX)$, $\exp(tY)$ and $\exp(tH)$, for $t \in \mathbb{R}$.
The real Lie algebra $\mathfrak{g}$ generated by $X, Y, H$ is called the Heisenberg algebra, and the group $G$ of real matrices of the form $\begin{pmatrix} 1 & \alpha & \beta \\ 0 & 1 & \delta \\ 0 & 0 & 1 \end{pmatrix}$ is called the Heisenberg group.
Show that the exponential map is a bijection of the Heisenberg algebra onto the Heisenberg group.
(b) What is the center of $\mathfrak{g}$ of $G$?
(c) More generally, we consider, for every positive integer $n$, the Lie algebra $\mathfrak{g}$ generated by $Q_k, P_k, H$, $k = 1, \ldots, n$, with the commutation relations
\[
\begin{align*}
[Q_k, H] &= [P_k, H] = [Q_k, Q_\ell] = [P_k, P_\ell] = 0, \\
[Q_k, P_\ell] &= \alpha \delta_{k\ell} H,
\end{align*}
\]
where $\alpha$ is a nonzero scalar. (The equations $[Q_k, P_\ell] = i\hbar \delta_{k\ell}$ are the Heisenberg relations.) Show that this Lie algebra has no finite-dimensional irreducible representation such that $\rho(H) \neq 0$, and that the irreducible finite-dimensional representations such that $\rho(H) = 0$ are one-dimensional.

Exercise 4.6 Differential of the exponential map.

Let $G$ be a Lie group and $\mathfrak{g}$ its Lie algebra. Show that $d_X(\exp)$, the differential at the point $X \in \mathfrak{g}$ of the map $\exp : \mathfrak{g} \to G$, satisfies
\[
\exp(-X)d_X(\exp) = \frac{1 - \exp(-\text{ad}_X)}{\text{ad}_X},
\]
where the right-hand side denotes the sum of a series. [Hint: Consider, for $X$ and $Y$ in $\mathfrak{g}$, $A_s(X, Y) = \exp(-sX)\frac{\partial}{\partial t}\exp(s(X + tY))|_{t=0}$ and calculate $\frac{\partial}{\partial s}A_s(X, Y)$.

Exercise 4.7 Killing form.

Let $\mathfrak{g}$ be a finite-dimensional Lie algebra on $K = \mathbb{R}$ or $\mathbb{C}$. The Killing form of $\mathfrak{g}$ is the $K$-bilinear form on $\mathfrak{g}$ defined by
\[
\forall X, Y \in \mathfrak{g}, \quad K(X, Y) = \text{Tr} (\text{ad}_X \circ \text{ad}_Y).
\]
(a) Show that for every $X, Y, Z \in \mathfrak{g}$,
\[
K([X, Y], Z) + K(Y, [X, Z]) = 0.
\]
(b) Let $G$ be a Lie group with Lie algebra $\mathfrak{g}$. Show that $K$ is an invariant bilinear form, that is, for every $g \in G$,

$$K(\text{Ad}_g X, \text{Ad}_g Y) = K(X, Y).$$

(c) Find the Killing form and determine its signature for each of the Lie algebras $\mathfrak{sl}(2, \mathbb{C})$, $\mathfrak{sl}(2, \mathbb{R})$, and $\mathfrak{so}(3)$.

**Exercise 4.8 Dimension of the symplectic groups.**

Let $J = \begin{pmatrix} 0 & I_n \\ -I_n & 0 \end{pmatrix}$. Calculate the dimension of the Lie algebra

$$\mathfrak{sp}(n, \mathbb{C}) = \{ X \in \mathfrak{sl}(2n, \mathbb{C}) \mid XJ + J^tX = 0 \}.$$ What are the dimensions of $\mathfrak{sp}(n, \mathbb{C})$ and of $\mathfrak{Sp}(n) = \mathfrak{sp}(n, \mathbb{C}) \cap \mathfrak{U}(2n)$?

**Exercise 4.9 Derivations and the adjoint representation.**

A derivation of a Lie algebra $\mathfrak{g}$ is a linear mapping of $\mathfrak{g}$ into $\mathfrak{g}$ satisfying, for every $X, Y \in \mathfrak{g}$,

$$D[X, Y] = [DX, Y] + [X, DY].$$

Let $G$ be a Lie group with Lie algebra $\mathfrak{g}$. Let $\mathfrak{h}$ be a Lie algebra. Show that if $\rho$ is a representation of $G$ on $\mathfrak{h}$ by automorphisms, then $D\rho$ is a representation of $\mathfrak{g}$ on $\mathfrak{h}$ by derivations. What can one say about the representations $\text{Ad}$ and $\text{ad}$?

**Exercise 4.10 Coadjoint representation.**

Let $G$ be a Lie group with Lie algebra $\mathfrak{g}$ and let $\mathfrak{g}^*$ be the dual vector space of $\mathfrak{g}$. By definition, the coadjoint representation of $G$ on $\mathfrak{g}^*$ is the dual of the adjoint representation. The coadjoint orbit of an element $\xi$ of $\mathfrak{g}^*$ is its orbit under the coadjoint action of $G$.

Find the coadjoint orbits in the case $G = \text{SO}(3)$.

**Exercise 4.11 Real forms.**

Show that $\mathfrak{so}(3), \mathfrak{su}(2), \mathfrak{so}(2, 1), \mathfrak{sl}(2, \mathbb{R})$ are real forms of $\mathfrak{sl}(2, \mathbb{C})$. Are they isomorphic as real Lie algebras?

**Exercise 4.12 The connected component of the identity of a Lie group.**

Let $G$ be a Lie group and let $G_0$ be the connected component of the identity of $G$.

(a) Show that $G_0$ is a normal subgroup of $G$.

(b) Show that the Lie groups $G$ and $G_0$ have the same Lie algebra.

**Exercise 4.13 Connected components.**

(a) Show that $\text{GL}(n, \mathbb{C})$, for $n \geq 2$, and $\text{U}(n)$, for $n \geq 1$, are connected. Find the connected component of the identity of $\text{GL}(n, \mathbb{R})$.

(b) Study the connected component of the identity of the Lorentz group. How many connected components does the Lorentz group have?
Exercise 4.14 Ideals of Lie algebras and normal subgroups.

Let $G$ be a connected Lie group with Lie algebra $\mathfrak{g}$, and let $H$ be a closed connected subgroup of $G$. Show that $H$ is normal if and only if the Lie algebra $\mathfrak{h}$ of $H$ is an ideal of $\mathfrak{g}$.

Exercise 4.15 Invariant measure on Lie groups.

Suppose that the elements of a Lie group $G$ of dimension $p$ are parametrized by $x = (x_1, x_2, \ldots, x_p)$. We denote by $g^{-1} \frac{dg}{dx}$ the matrix whose columns are the components of the vectors $g^{-1}(x) \frac{dg}{dx_k}(x), k = 1, 2, \ldots, p$, in a basis of $\mathfrak{g}$. Show that $|\det(g^{-1} \frac{dg}{dx})|$ is a left-invariant volume element on $G$. 

Élie Cartan, who was born in Dolomieu (Isère) in 1869 and died in Paris in 1951, is famous for his work on Lie groups and algebras and his fundamental contributions to differential geometry. Here he is on vacation in 1931, with two of his sons, his daughter, Hélène, and a nephew. On the far left is his son Henri (1904–2008), one of the founders of the Bourbaki group and a great mathematician of the twentieth century.

(Private collection)
Chapter 5

Lie Groups SU(2) and SO(3)

1 The Lie Algebras \( \mathfrak{su}(2) \) and \( \mathfrak{so}(3) \)

We know that \( \mathfrak{su}(2) \) and \( \mathfrak{so}(3) \) are real Lie algebras of dimension 3. We shall show that they are isomorphic by showing that there are bases of each in which the commutation relations are the same.

1.1 Bases of \( \mathfrak{su}(2) \)

The Lie algebra \( \mathfrak{su}(2) = \{ X \in \mathfrak{gl}(2, \mathbb{C}) \mid iX + X = 0, \text{Tr}X = 0 \} \) is the real vector space of dimension 3 of traceless anti-Hermitian \( 2 \times 2 \) complex matrices.

(a) The three linearly independent matrices

\[
\begin{align*}
\xi_1 &= \frac{1}{2} \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \\
\xi_2 &= \frac{1}{2} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \\
\xi_3 &= \frac{1}{2} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix},
\end{align*}
\]

form a basis over \( \mathbb{R} \) of \( \mathfrak{su}(2) \) and satisfy the commutation relations

\[ [\xi_k, \xi_\ell] = \xi_m, \]

where \( k, \ell, m \) is a cyclic permutation of 1, 2, 3.

(b) In physics one considers the Pauli matrices which are Hermitian matrices

\[
\begin{align*}
\sigma_1 &= -2i\xi_1 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \\
\sigma_2 &= 2i\xi_2 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}, \\
\sigma_3 &= -2i\xi_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.
\end{align*}
\]

They satisfy the commutation relations

\[ [\sigma_k, \sigma_\ell] = 2i\sigma_m. \]

One also sometimes uses the matrices

\[
\begin{align*}
\tilde{\sigma}_1 &= \frac{1}{2} \sigma_1 = -i\xi_1, \\
\tilde{\sigma}_2 &= \frac{1}{2} \sigma_2 = i\xi_2, \\
\tilde{\sigma}_3 &= \frac{1}{2} \sigma_3 = -i\xi_3,
\end{align*}
\]

which satisfy the commutation relations

\[ [\tilde{\sigma}_k, \tilde{\sigma}_\ell] = i\tilde{\sigma}_m. \]
(c) We also introduce the matrices
\[ J_k = i\xi_k, \]
which satisfy the commutation relations,
\[ [J_k, J_k] = iJ_m. \]

We also consider the matrices
\[ J_3 = \frac{1}{2} \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \]
\[ J_+ = J_1 + iJ_2 = \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix}, \quad J_- = J_1 - iJ_2 = \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix}. \]

We have
\[ J_3 = i\xi_3 = -\bar{\sigma}_3 = -\frac{1}{2}\sigma_3, \]
\[ J_\pm = J_1 \pm iJ_2 = i\xi_1 \mp \xi_2 = -\bar{\sigma}_1 \pm i\bar{\sigma}_2 = \frac{1}{2}(-\sigma_1 \pm i\sigma_2), \]
and so
\[ \xi_3 = -iJ_3, \quad \xi_1 = -\frac{i}{2}(J_+ + J_-), \quad \xi_2 = -\frac{1}{2}(J_+ - J_-). \]
The matrices \( J_3, J_+, J_- \) satisfy the commutation relations,
\[ [J_+, J_-] = 2J_3, \quad [J_3, J_\pm] = \pm J_\pm. \]

(d) Finally, we introduce the basis of \( \mathfrak{su}(2) \),
\[ I = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \quad J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad K = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}. \]

We see immediately that
\[ I^2 = J^2 = K^2 = -I, \]
\[ IJ = K = -JK, \quad JK = I = -KJ, \quad KI = J = -IK, \]
and the commutation relations of \( \mathfrak{su}(2) \) can thus be written
\[ [I, J] = 2K, \quad [J, K] = 2I, \quad [K, I] = 2J. \]

We have
\[ I = 2\xi_1 = 2i\bar{\sigma}_1 = i\sigma_1 = -2iJ_1, \]
\[ J = 2\xi_2 = -2i\bar{\sigma}_2 = -i\sigma_2 = -2iJ_2, \]
\[ K = 2\xi_3 = 2i\bar{\sigma}_3 = i\sigma_3 = -2iJ_3. \]
A matrix $X$ of $\mathfrak{su}(2)$ can be written $X = x_1 \mathcal{I} + x_2 \mathcal{J} + x_3 \mathcal{K}$, i.e.,

$$X = \begin{pmatrix}
i x_3 & -x_2 + i x_1 \\
x_2 + i x_1 & -i x_3
\end{pmatrix},$$

where $x_1, x_2, x_3$ are real numbers. We have then

$$\det X = \| \vec{X} \|^2,$$

where $\| \vec{X} \|$ is the Euclidean norm of the vector $\vec{X}$ with components $(x_1, x_2, x_3)$.

**Interpretation in terms of quaternions.** Let $\mathbb{H}$ be the associative algebra of the quaternions, a vector space of dimension 4, with basis $(1, i, j, k)$, with the multiplication defined by

$$i^2 = j^2 = k^2 = -1, \quad ij = -ji = k, \quad jk = -kj = i, \quad ki = -ik = j.$$

The map $i \mapsto \mathcal{I}, j \mapsto \mathcal{J}, k \mapsto \mathcal{K}$ defines a bijection of the vector space $\mathfrak{su}(2)$ onto the vector subspace of $\mathbb{H}$ generated by $i, j, k$, called the vector space of *pure quaternions*, and denoted by $\mathbb{H}_0$. The vector subspace $\mathbb{H}_0$ is not a subalgebra of the associative algebra $\mathbb{H}$, but $\mathbb{H}_0$ is a Lie algebra under the commutator, and the bijection above is an isomorphism of Lie algebras.

**Remark.** All the triples of matrices considered above form bases over $\mathbb{C}$ of $(\mathfrak{su}(2))^\mathbb{C} = \mathfrak{sl}(2, \mathbb{C})$. While the $\xi_k$ and the matrices $\mathcal{I}, \mathcal{J}, \mathcal{K}$ belong to $\mathfrak{su}(2)$, the Pauli matrices $\sigma_k$ and the matrices $J_k$ belong to $i\mathfrak{su}(2)$.

### 1.2 Bases of $\mathfrak{so}(3)$

The Lie algebra $\mathfrak{so}(3)$ is the vector space of antisymmetric real $3 \times 3$ matrices. We have already seen that the matrices

$$\eta_1 = \begin{pmatrix}0 & 0 & 0 \\0 & 0 & -1 \\
0 & 1 & 0\end{pmatrix}, \quad \eta_2 = \begin{pmatrix}0 & 0 & 1 \\0 & 0 & 0 \\
-1 & 0 & 0\end{pmatrix}, \quad \eta_3 = \begin{pmatrix}0 & -1 & 0 \\1 & 0 & 0 \\
0 & 0 & 0\end{pmatrix},$$

form a basis of this Lie algebra, with the commutation relations

$$[\eta_k, \eta_l] = \eta_m.$$

It is clear that $\eta_k \mapsto e_k$, where $(e_1, e_2, e_3)$ is the canonical basis of $\mathbb{R}^3$, defines an isomorphism of the Lie algebra $\mathfrak{so}(3)$ onto the Lie algebra $(\mathbb{R}^3, \wedge)$.

On the other hand,

$$\mathfrak{su}(2) \approx \mathfrak{so}(3).$$

More precisely, an isomorphism of Lie algebras is realized by the $\mathbb{R}$-linear map defined by $\xi_k \mapsto \eta_k$. From the fact that $\mathfrak{su}(2)$ and $\mathfrak{so}(3)$ are isomorphic, we deduce that $(\mathfrak{so}(3))^\mathbb{C} = \mathfrak{sl}(2, \mathbb{C})$.

We may also consider the matrices

$$\tilde{J}_k = i\eta_k.$$

In the preceding isomorphism, $\tilde{\sigma}_1 \mapsto -\tilde{\mathcal{J}}_1, \tilde{\sigma}_2 \mapsto \tilde{\mathcal{J}}_2, \tilde{\sigma}_3 \mapsto -\tilde{\mathcal{J}}_3$. 
1.3 Bases of $\mathfrak{sl}(2, \mathbb{C})$

Other than the bases already described above, the most frequently used basis is

$$H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad X_+ = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad X_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},$$

which satisfies the commutation relations

$$[H, X_\pm] = \pm 2X_\pm, \quad [X_+, X_-] = H.$$

We have

$$H = -2J_3 = -2i\xi_3 = 2\tilde{\sigma}_3 = \sigma_3,$$

$$X_\pm = -J_\mp = -J_1 \pm iJ_2 = -(i\xi_1 \pm \xi_2) = \tilde{\sigma}_1 \pm i\tilde{\sigma}_2 = \frac{1}{2}(\sigma_1 \pm i\sigma_2),$$

and thus

$$J_3 = -\frac{1}{2}H, \quad J_\pm = -X_\mp,$$

and

$$I = i(X_+ + X_-), \quad J = -(X_+ - X_-), \quad K = iH.$$

2 The Covering Morphism of SU(2) onto SO(3)

We shall see that although the Lie algebras of the Lie groups SO(3) and SU(2) are isomorphic, the groups themselves are not. The one, SU(2), is connected and simply connected, but the other, SO(3), is connected but not simply connected, and there is a surjective group morphism of the first onto the second, whose kernel consists of the elements $I$ and $-I$ of SU(2).

2.1 The Lie Group SO(3)

Every orthogonal transformation of $\mathbb{R}^3$ of determinant +1 leaves a unit vector $a$ of $\mathbb{R}^3$ invariant. This is then a rotation through an angle $t \in \mathbb{R}/2\pi \mathbb{Z}$, denoted by Rot$(a, t)$. Thus an element of SO(3) is determined by $a \in \mathbb{R}^3, ||a|| = 1$, and $t \in [0, 2\pi]$. The image of an element $x \in \mathbb{R}^3$ by Rot$(a, t)$ is

$$\text{Rot}(a, t)(x) = x + (1 - \cos t)a \wedge (a \wedge x) + \sin t \ \alpha \wedge x. \quad (2.1)$$

For the proof, we observe first that if $x$ is orthogonal to $a$, then

$$\text{Rot}(a, t)(x) = \cos t \ x + \sin t \ a \wedge x.$$ 

Next we decompose any $x$ as $\lambda a + \mu b$, where $b$ is orthogonal to $a$, and we exploit the linearity of Rot$(a, t)$. Hence

$$\text{Rot}(a, t)(x) = \cos t \ x + (1 - \cos t)(x \ | \ a)a + \sin t \ a \wedge x.$$ 

Finally, we use the triple product formula, $u \wedge (v \wedge w) = (u \ | \ w)v - (u \ | \ v)w$, which gives $(x \ | \ a)a = x + a \wedge (a \wedge x)$, which proves (2.1).
Proposition 2.1. Two rotations are conjugate in SO(3) if and only if they have equal or opposite angles.

Proof. It is clear that for $t \neq 0$, the pair $(a', t')$ defines the same rotation as the pair $(a, t)$ if and only if $(a', t') = (a, t)$ or $(a', t') = (-a, -t)$. We shall now prove that rotations $\text{Rot}(a, t)$ and $\text{Rot}(a', t')$ are conjugate in SO(3) if and only if $t' = \pm t$. In fact, if a rotation $R$ leaves $a$ invariant, then for each $g \in \text{SO}(3)$, the rotation $gRg^{-1}$ leaves $ga$ invariant. More precisely, it follows from the preceding formulas that

$$\forall g \in \text{SO}(3), \quad g \text{ Rot}(a, t) g^{-1} = \text{Rot}(ga, t), \quad (2.2)$$

for $x \in \mathbb{R}^3$. Therefore, if $R' = \text{Rot}(a', t')$ is a rotation conjugate to $R = \text{Rot}(a, t)$ by an element $g \in \text{SO}(3)$, then $\text{Rot}(a', t') = \text{Rot}(ga, t)$, and therefore $R$ and $R'$ have equal or opposite angles. Conversely, each rotation $\text{Rot}(a', t)$ is conjugate to $\text{Rot}(a, t)$ by an element $g \in \text{SO}(3)$ such that $a' = ga$, and each rotation $\text{Rot}(a', -t)$ is conjugate to $\text{Rot}(a, t)$ by an element $g \in \text{SO}(3)$ such that $-a' = ga$. □

Surjectivity of the exponential map of $\mathfrak{so}(3)$ onto SO(3). Let $\eta_k$ be the infinitesimal generators of the one-parameter groups of rotations around the axes $e_k$, $k = 1, 2, 3$. By definition,

$$\exp(t \eta_k) = \text{Rot}(e_k, t).$$

Let $a$ be any unit vector in $\mathbb{R}^3$. We choose $k = 1, 2, \text{ or } 3$, and let $g$ be an element of SO(3) such that $a = g(e_k)$. Then

$$\text{Rot}(a, t) = g \text{ Rot}(e_k, t) g^{-1} = g \exp(t \eta_k) g^{-1} = \exp(t g \eta_k g^{-1}).$$

By Theorem 5.1 (iii) of Chapter 4, the element $g \eta_k g^{-1}$ belongs to $\mathfrak{so}(3)$. We have thus shown that the exponential map is surjective from $\mathfrak{so}(3)$ onto SO(3). We deduce that SO(3) is arc-connected, hence connected, and that it is the connected component of the identity of O(3). We remark that the exponential map is clearly not injective from $\mathfrak{so}(3)$ into SO(3) because for $X = \eta_k$ ($k = 1, 2$ or $3$) and $\ell$ integer, $\exp((t + 2\ell \pi)X) = \exp(tX)$.

Identification of $\mathfrak{so}(3)$ with $\mathbb{R}^3$. Let $a \mapsto M_a$ be the $\mathbb{R}$-linear map from $\mathbb{R}^3$ onto $\mathfrak{so}(3)$ defined by $e_k \mapsto \eta_k$. The equation $M_{e_k}(x) = \eta_k(x) = e_k \wedge x$ implies by linearity that $M_a(x) = a \wedge x$, for every $x \in \mathbb{R}^3$, and for $g \in \text{SO}(3)$, $M_{ga}(x) = ga \wedge x = g(a \wedge g^{-1}x) = gM_aga^{-1}(x)$. Thus

$$\forall g \in \text{SO}(3), \quad \forall a \in \mathbb{R}^3, \quad M_{ga} = \text{Ad}_g M_a.$$

Proposition 2.2. For each $a \in \mathbb{R}^3$ of unit norm and for every $t \in \mathbb{R}$,

$$\exp(t M_a) = \text{Rot}(a, t). \quad (2.3)$$

Proof. The two sides are one-parameter subgroups of SO(3). By (2.1),

$$\forall x \in \mathbb{R}^3, \quad \frac{d}{dt} \text{Rot}(a, t)(x)|_{t=0} = a \wedge x,$$
while
\[ \forall x \in \mathbb{R}^3, \quad \frac{d}{dt} \exp(tM_a)(x) \bigg|_{t=0} = M_a(x), \]
which proves (2.3).

\[ \square \]

Remark. Despite the differences of notation, formula (2.3) is the same as a formula to be found in physics books, e.g., (1.48) in Blaizot–Tolédano (1997),
\[ D(\vec{u}, \alpha) = e^{-i\alpha \vec{u} \cdot \vec{J}}, \]
where \( \vec{J} \) denotes the triple of matrices \( i\eta_1, i\eta_2, i\eta_3 \), which we have denoted by \( \hat{J}_1, \hat{J}_2, \hat{J}_3 \) (but which are denoted by \( J_1, J_2, J_3 \) in that book). This equation says that the rotation determined by the unit vector \( \vec{u} = (u_1, u_2, u_3) \) and angle \( \alpha \) is the exponential of the matrix \(-i\alpha(u_1\hat{J}_1 + u_2\hat{J}_2 + u_3\hat{J}_3)\). Since this matrix is equal to \( \alpha(u_1\eta_1 + u_2\eta_2 + u_3\eta_3) \), this equation is in fact the same as (2.3). In Tung (1985), this equation is (7.2-8), written
\[ R_n(\psi) = e^{-i\psi J_k n^k}, \]
where \( n \) is a unit vector with components \( n^1, n^2, n^3 \), and \( \psi \) is the angle of the rotation.

2.2 The Lie Group SU(2)

The Lie group \( \text{SU}(2) = \{ A \in \text{GL}(2, \mathbb{C}) \mid A^\dagger A = I, \det A = 1 \} \) is diffeomorphic to the sphere \( S^3 \subset \mathbb{R}^4 \) because
\[ \text{SU}(2) = \left\{ \begin{pmatrix} a & b \\ -\bar{b} & \bar{a} \end{pmatrix} \mid a, b \in \mathbb{C}, |a|^2 + |b|^2 = 1 \right\}. \]

In fact, for a matrix \( A = \begin{pmatrix} a & b \\ -\bar{b} & \bar{a} \end{pmatrix} \), the equations \( A^\dagger A = I \) and \( \det A = 1 \) imply that \( |a|^2 + |b|^2 = 1, \quad |c|^2 + |d|^2 = 1, \quad ad - bc = 1, \quad a\bar{c} + b\bar{d} = 0, \) whence \( ad\bar{c} + b\bar{d}c = 0 \), and similarly, \( d = \bar{a} \). The elements of the Lie group \( \text{SU}(2) \) thus depend on three independent real parameters. Like the sphere \( S^3 \), the group \( \text{SU}(2) \) is compact, connected, and simply connected.

Every unitary matrix is diagonalizable by means of a unitary matrix. Because the eigenvalues of a unitary matrix are of modulus 1, for every \( A \in \text{SU}(2) \), there are a real number \( t \) and a special unitary matrix \( g \) such that
\[ A = g \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix} g^{-1}. \]

Furthermore \( \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix} \) and \( \begin{pmatrix} e^{-it} & 0 \\ 0 & e^{it} \end{pmatrix} \) are conjugate via \( \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \) in \( \text{SU}(2) \).

**Surjectivity of the exponential map of \( \text{su}(2) \) on \( \text{SU}(2) \).** Let \( A = g \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix} g^{-1} \) be a matrix of \( \text{SU}(2) \). From the equation
\[ \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix} = \exp(tK), \]
we deduce that
\[ A = \exp(t g K g^{-1}), \]
with \( g K g^{-1} \in \mathfrak{su}(2) \). Thus the exponential map is surjective from \( \mathfrak{su}(2) \) onto \( \text{SU}(2) \).

**Identification of \( \mathfrak{su}(2) \) with \( \mathbb{R}^3 \).** Let \( a \mapsto X_a \) be the \( \mathbb{R} \)-linear map from \( \mathbb{R}^3 \) onto \( \mathfrak{su}(2) \) defined by
\[
e_1 \mapsto I, \quad e_2 \mapsto J, \quad e_3 \mapsto K.
\]
Then (see formula (1.1))
\[ \det X_a = \|a\|^2, \]
and in addition,
\[ (X_a)^2 = -(\det X_a)I. \]

We deduce the following lemma:

**Lemma 2.3.** For each \( X \in \mathfrak{su}(2) \), \( X^2 = -(\det X)I \).

**Proposition 2.4.** For each \( X \in \mathfrak{su}(2) \) such that \( \det X = 1 \), and for every \( t \in \mathbb{R} \),
\[ \exp(tX) = \cos t I + \sin t X. \]

**Proof.** It is clear that the two sides have \( X \) for derivative at \( t = 0 \). It thus suffices to show that if \( \det X = 1 \), the map \( t \mapsto \cos t I + \sin t X \) is a one-parameter subgroup of \( \text{GL}(2, \mathbb{C}) \). For \( t \) and \( s \in \mathbb{R} \),
\[
(cos t I + \sin t X)(\cos s I + \sin s X) = \cos t \cos s I + \sin t \sin s X^2 + (\sin t \cos s + \cos t \sin s)X.
\]
Thus by the lemma, if \( \det X = 1 \), then
\[
(cos t I + \sin t X)(\cos s I + \sin s X) = \cos(t + s)I + \sin(t + s)X.
\]
One can also use the definition of the exponential as a series of matrices and the preceding lemma.

As a consequence of Proposition 2.4, we see that each matrix of \( \text{SU}(2) \) can be written \( \alpha_0 I + \alpha_1 J + \alpha_2 J + \alpha_3 K \), where the vector \( (\alpha_0, \alpha_1, \alpha_2, \alpha_3) \) of \( \mathbb{R}^4 \) has norm 1. Thus \( \text{SU}(2) \) is identified with the group of quaternions of unit norm.

### 2.3 Projection of \( \text{SU}(2) \) onto \( \text{SO}(3) \)

We consider the adjoint representation of \( \text{SU}(2) \) on \( \mathfrak{su}(2) \),
\[ \text{Ad} : \text{SU}(2) \to \text{GL}(\mathfrak{su}(2)). \]
When we identify \( \mathfrak{su}(2) \) with \( \mathbb{R}^3 \) by means of the isomorphism \( a \mapsto X_a \), the map \( \text{Ad} \) is identified with a map
\[ \varphi : \text{SU}(2) \to \text{GL}(3, \mathbb{R}). \]
This is the map that to \( g \in \text{SU}(2) \) associates the matrix of \( \text{Ad}_g \) in the basis \((\mathcal{I}, \mathcal{J}, \mathcal{K})\) of \( \text{su}(2) \).

For each \( g \in \text{SU}(2) \), \( \text{Ad}_g : \text{su}(2) \to \text{su}(2) \) is the map \( X \mapsto gXg^{-1} \) that preserves determinants. By (1.1), in the identification of \( \text{su}(2) \) with \( \mathbb{R}^3 \), the determinant of a matrix corresponds to the square of the Euclidean norm of the vector; hence for every \( g \in \text{SU}(2) \), \( \varphi(g) \) preserves the norm, and thus \( \varphi(\text{SU}(2)) \subset \text{O}(3) \). In fact, since \( \varphi \) is continuous and \( \text{SU}(2) \) is connected, \( \varphi(\text{SU}(2)) \subset \text{SO}(3) \). We know that the map \( \varphi : \text{SU}(2) \to \text{SO}(3) \) is a morphism of groups. We shall show that the morphism \( \varphi \) is surjective from \( \text{SU}(2) \) onto \( \text{SO}(3) \), and we shall determine its kernel.

**Proposition 2.5.** (i) In the basis \((\mathcal{I}, \mathcal{J}, \mathcal{K})\) of \( \text{su}(2) \), the matrix of \( \text{ad}_{\xi_k} \) is \( \eta_k \), for \( k = 1, 2, 3 \).

(ii) For each \( t \in \mathbb{R} \),
\[
\varphi(\exp(t\xi_k)) = \exp(t\eta_k).
\]

(iii) For each \( a \in \mathbb{R}^3 \) of unit norm, and for every \( t \in \mathbb{R} \),
\[
\varphi(\exp(tX_a)) = \text{Rot}(a, 2t).
\]

(iv) The map \( \varphi \) is surjective.

**Proof.** (i) It suffices to write \( \text{ad}_{\xi_k}(\xi_\ell) = [\xi_k, \xi_\ell] = \xi_m \), and we immediately obtain the matrix of \( \text{ad}_{\xi_k} \) in the basis \((\xi_1, \xi_2, \xi_3)\), which is also its matrix in the basis \((\mathcal{I}, \mathcal{J}, \mathcal{K})\).

(ii) is the consequence of (i).

(iii) Let the components of \( a \in \mathbb{R}^3 \) be \( a_1, a_2, a_3 \). Then, by definition, \( X_a = a_1\mathcal{I} + a_2\mathcal{J} + a_3\mathcal{K} = 2(a_1\xi_1 + a_2\xi_2 + a_3\xi_3) \). Thus the matrix of \( \text{ad}_{X_a} \) in the basis \((\mathcal{I}, \mathcal{J}, \mathcal{K})\) is \( 2(a_1\eta_1 + a_2\eta_2 + a_3\eta_3) = 2M_a \). Therefore the matrix of \( \text{Ad}_{\exp(tX_a)} \) in this basis is \( \exp(2tM_a) \). If \( a \) is of unit norm, then it is \( \text{Rot}(a, 2t) \).

(iv) is the consequence of (iii). \( \square \)

The kernel of \( \text{Ad} \) is \( \{ g \in \text{SU}(2) \mid \text{Ad}_g = \text{Id}_{\text{su}(2)} \} \). Let \( g = \begin{pmatrix} a & b \\ -\overline{b} & \overline{a} \end{pmatrix} \) be such that \( g\mathcal{K} = \mathcal{K}g \), \( g\mathcal{I} = \mathcal{I}g \), \( g\mathcal{J} = \mathcal{J}g \). One sees that \( b = 0 \) and \( a \) is real. Because \( \det g = 1 \), we have \( g = I \) or \( g = -I \). Thus \( \text{Ker}\varphi = \{ I, -I \} \). The morphism \( \varphi \) is thus not injective, since its kernel contains two elements.

Because \( \varphi \) is continuous and surjective, and since \( \text{SU}(2) \) is simply connected, we can state the following result:

**Proposition 2.6.** The group \( \text{SU}(2) \) is the double-sheeted universal cover of the group \( \text{SO}(3) \).

**References**

The books of Rossmann (2002) and of Hall (2003), among many others, study the group of rotations and its universal cover \( \text{SU}(2) \). Already in 1847, in a paper published in the *Proceedings of the Irish Royal Academy*,...
William Rowan Hamilton (1805–1865) applied the theory of quaternions to the problem of the composition of rotations in space.

Exercises

Exercise 5.1 Conjugate rotations

We use the notation of Section 2.1. Let \( x \) be a vector in \( \mathbb{R}^3 \) and let \( g \mapsto g(t) \) be a one-parameter subgroup of \( \text{SO}(3) \), with infinitesimal generator \( M_x \).

(a) Show that the rotations \( g(t) \) leave the vector \( x \) of \( \mathbb{R}^3 \) invariant.
(b) For \( g_0 \in \text{SO}(3) \), show that \( t \mapsto g_0g(t)g_0^{-1} \) is a one-parameter subgroup of \( \text{SO}(3) \) with infinitesimal generator \( M_{g_0x} \).

Exercise 5.2 Eigenvalues \(-1\) and \(1\) of \( \text{Ad}_g \).

(a) Show that the endomorphism \( \text{Ad}_g + \text{Id}_{\mathfrak{su}(2)} \) of \( \mathfrak{su}(2) \) is invertible for every \( g \in \text{SU}(2) \) except for a set of measure zero. Find this set of measure zero.
(b) Find the dimension of the kernel of \( \text{Ad}_g - \text{Id}_{\mathfrak{su}(2)} \) as a function of \( g \in \text{SU}(2) \).

Exercise 5.3 An isomorphism of Lie algebras.

Show that the Lie algebra \( \mathfrak{su}(2) \times \mathfrak{su}(2) \) is isomorphic to the Lie algebra \( \mathfrak{so}(4) \).

Exercise 5.4 Haar measure on the group \( \text{SU}(2) \).

We parametrize \( \text{SU}(2) \) off a set of measure zero by setting, for an element \( g \in \text{SU}(2) \), \( g = \left( \begin{smallmatrix} a & b \\ -b & \overline{a} \end{smallmatrix} \right) \), \( a = a_1 + ia_2 \) and \( b = b_1 + ib_2 \), and

\[
\begin{align*}
a_1 &= \cos \theta_3, & a_2 &= \sin \theta_3 \cos \theta_2, & b_1 &= \sin \theta_3 \sin \theta_2 \cos \theta_1, & b_2 &= \sin \theta_3 \sin \theta_2 \sin \theta_1,
end{align*}
\]

for \( \theta_1 \in (0, 2\pi) \), \( \theta_2 \in (0, \pi) \), \( \theta_3 \in (0, \pi) \).

(a) Show that the Haar integral on \( \text{SU}(2) \) can be written

\[
I(f) = \frac{1}{2\pi^2} \int_O f(\theta_1, \theta_2, \theta_3) \sin^2 \theta_3 \sin \theta_2 d\theta_1 \, d\theta_2 \, d\theta_3, 
\]

where \( O = (0, 2\pi) \times (0, \pi) \times (0, \pi) \).

(b) Set \( \theta_3 = t \). Show that the Haar integral of a class function \( f \) is

\[
\frac{2}{\pi} \int_0^\pi f(t) \sin^2 t \, dt.
\]
Exercise 5.5 Euler angles and Haar measure on the group SO(3).

(a) Show that each rotation $g \in \text{SO}(3)$ can be written

$$g = \exp(\alpha \eta_3) \exp(\beta \eta_1) \exp(\gamma \eta_3)$$

with $0 \leq \alpha < 2\pi$, $0 \leq \beta \leq \pi$, $0 \leq \gamma < 2\pi$, uniquely if $\beta \neq 0$ and $\beta \neq \pi$. The angles $\alpha$, $\beta$, $\gamma$ are called the Euler angles of the rotation.

(b) Show that the Haar integral of SO(3) can be written

$$I(f) = \frac{1}{8\pi^2} \int_{\Omega_0} f(\alpha, \beta, \gamma) \sin \beta \, d\alpha \, d\beta \, d\gamma,$$

where $\Omega_0 = (0, 2\pi) \times (0, \pi) \times (0, 2\pi)$.

Exercise 5.6 Euler angles and Haar measure on the group SU(2).

Let $\Omega = (0, 2\pi) \times (0, \pi) \times (-2\pi, 2\pi)$.

(a) Show that for every pair of complex numbers $a$ and $b$ such that $|a|^2 + |b|^2 = 1$, $\text{Im}(a) \neq 0$, and $\text{Re}(b) \neq 0$, there is a unique triple $(\phi, \theta, \psi) \in \Omega$ such that $a = \cos \frac{\theta}{2} e^{i\phi+\psi/2}$, $b = i \sin \frac{\theta}{2} e^{i\phi-\psi/2}$. Conclude that off a set of measure zero of SU(2), each matrix $g = (\begin{smallmatrix} a & b \\ -\bar{b} & \bar{a} \end{smallmatrix}) \in \text{SU}(2)$ can be written in one and only one way as

$$g = \exp(\phi \xi_3) \exp(\theta \xi_1) \exp(\psi \xi_3),$$

with $(\phi, \theta, \psi) \in \Omega$. Show that the image of $g(\phi, \theta, \psi)$ under the morphism $\varphi$ of SO(3) onto SU(2) is the rotation with Euler angles $(\phi, \theta, \psi)$.

(b) Show that the Haar integral on SU(2) can be written

$$I(f) = \frac{1}{16\pi^2} \int_{\Omega} f(\phi, \theta, \psi) \sin \theta \, d\phi \, d\theta \, d\psi.$$
Chapter 6

Representations of SU(2) and SO(3)

To study the representations of the Lie group SU(2), we first study those of its Lie algebra \( \mathfrak{su}(2) \), by studying the representations of the Lie algebra \( \mathfrak{sl}(2, \mathbb{C}) \). In fact, by Proposition 1.4 of Chapter 4, if \( \mathfrak{g}^C \) is the complexification of a real Lie algebra \( \mathfrak{g} \), there is a bijective correspondence between irreducible representations of \( \mathfrak{g} \) and of \( \mathfrak{g}^C \). In order to determine the irreducible representations of \( \mathfrak{su}(2) \), we shall thus study those of \( \mathfrak{sl}(2, \mathbb{C}) \). We recall that by our convention, a representation is a representation on a finite-dimensional complex vector space.

1 Irreducible Representations of \( \mathfrak{sl}(2, \mathbb{C}) \)

1.1 The Representations \( D^j \)

We consider \( \mathfrak{sl}(2, \mathbb{C}) \) equipped with the basis

\[
H = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad X_+ = \begin{pmatrix} 0 & 0 \\ 0 & 0 \end{pmatrix}, \quad X_- = \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},
\]

in which the commutation relations can be written

\[
[H, X_\pm] = \pm 2X_\pm, \\
[X_+, X_-] = H. \tag{1.1}
\]

Let \((E, R)\) be an irreducible finite-dimensional representation of \( \mathfrak{sl}(2, \mathbb{C}) \). The operator \( R(H) \) has at least one eigenvalue \( \lambda \) and an eigenvector \( v \) for this eigenvalue that by definition satisfies \( v \neq 0 \) and

\[
R(H)v = \lambda v.
\]

By the commutation relations (1.1),

\[
R(H)R(X_+)v = (R(X_+)R(H) + 2R(X_+))v = (\lambda + 2)R(X_+)v \tag{1.2}
\]
and
\[ R(H)R(X_-)v = (R(X_-)R(H) - 2R(X_-))v = (\lambda - 2)R(X_-)v. \] (1.3)

Because there can be no more than a finite number of distinct eigenvalues of \( R(H) \), there are an eigenvalue \( \lambda_0 \) and an associated eigenvector \( v_0 \) such that 
\[ R(H)v_0 = \lambda_0 v_0, \] (1.4)

Then we set, for \( k \in \mathbb{N} \),
\[ v_k = R(X_-)^k v_0. \]

By iterating equation (1.3), we obtain
\[ R(H)v_k = (\lambda_0 - 2k)v_k. \] (1.5)

The nonzero vectors \( v_k \) are thus eigenvectors of \( R(H) \) with distinct eigenvalues.

We shall show, by induction on \( k \) that for any positive integer \( k \),
\[ R(X_+)v_k = k(\lambda_0 - k + 1)v_{k-1}. \]

The equation is satisfied for \( k = 1 \) because by (1.1) and (1.4),
\[ R(X_+)v_1 = R(X_+)R(X_-)v_0 = R(H)v_0 = \lambda_0 v_0. \]

Assume that the equation holds for \( k \). Using the hypothesis \( v_{k+1} = R(X_-)v_k \) and the second equation of (1.1), we obtain
\[ R(X_+)v_{k+1} = R(X_+)R(X_-)v_k = (R(X_-)R(X_+) + R(H))v_k \]
\[ = R(X_-)k(\lambda_0 - k + 1)v_{k-1} + (\lambda_0 - 2k)v_k \]
\[ = (k(\lambda_0 - k + 1) + \lambda_0 - 2k)v_k = (k + 1)(\lambda_0 - k)v_k, \]

which proves the equation.

Since the nonzero vectors \( v_k \) are linearly independent and the vector space \( E \) was assumed finite-dimensional, there is an integer \( n \) such that
\[ v_0 \neq 0, \quad v_1 \neq 0, \quad \ldots, \quad v_n \neq 0, \quad v_{n+1} = 0. \]

Hence, writing \( R(X_+)v_{n+1} = 0 \), we have
\[ \lambda_0 = n. \]

One can then verify that for every \( k \in \mathbb{N} \),
\[ [R(X_+), R(X_-)]v_k = R(H)v_k, \quad [R(H), R(X_\pm)]v_k = \pm 2R(X_\pm)v_k. \]

The vectors, \( v_0, v_1, \ldots, v_n \) generate a subspace of \( E \) invariant under \( R \), and since the desired representation is irreducible, they generate \( E \), which is thus
of dimension \(n + 1\). In summary, we have found a representation \((E^{(n)}, R^{(n)})\) of dimension \(n + 1\) of \(\mathfrak{sl}(2, \mathbb{C})\) and a basis \(v_0, v_1, \ldots, v_n\) of \(E^{(n)}\) such that

\[
\begin{align*}
R^{(n)}(H)v_k &= (n - 2k)v_k, \\
R^{(n)}(X_-)v_k &= v_{k+1}, \\
R^{(n)}(X_+)v_k &= k(n - k + 1)v_{k-1},
\end{align*}
\]

for \(0 \leq k \leq n\), and \(v_{-1} = 0, v_{n+1} = 0\). Let us show that the representation \((E^{(n)}, R^{(n)})\) is irreducible. We suppose that \(u\) is a nonzero vector in a vector subspace \(F\) of \(E^{(n)}\), invariant under \(R^{(n)}\). Then

\[
u = \sum_{k=0}^{n} u_kv_k, \quad u_k \in \mathbb{C}.
\]

Suppose \(u_{k_0} \neq 0, u_{k_0+1} = \cdots = u_n = 0\), where \(0 < k_0 \leq n\). Then \((R^{(n)}(X_+))^{k_0}u\) is proportional to \(v_0\) with a nonzero coefficient. Thus \(v_0\) belongs to \(F\), and consequently so do the \(v_k\), for \(k = 0, \ldots, n\). Thus each nontrivial invariant subspace coincides with the entire space. On the other hand, the proof above showed that every irreducible finite-dimensional representation of \(\mathfrak{sl}(2, \mathbb{C})\) is of the form \((E^{(n)}, R^{(n)})\), for a certain \(n \in \mathbb{N}\).

**Proposition 1.1.** The irreducible finite-dimensional representations of \(\mathfrak{sl}(2, \mathbb{C})\) are the \((E^{(n)}, R^{(n)})\), \(n \in \mathbb{N}\).

Often, particularly in physics texts, one writes simply \(Hv_k, X_-v_k, X_+v_k\), where the name of the representation is understood. Physicists set \(n = 2j\), with \(j\) integer or half-integer, and they prefer the basis \(J_3, J_+, J_-\) of \(\mathfrak{sl}(2, \mathbb{C})\). They use \((E^j, D^j)\) to denote the representation \((E^{(2j)}, R^{(2j)})\) and they use the basis of \(E^j = E^{(2j)}\) indexed by the number \(m, -j \leq m \leq j\) (\(m\) is integer if \(j\) is integer, half-integer if \(j\) is half-integer), denoted by \(|j, m\rangle\) and called the *standard basis* of the representation \(D^j\), defined by

\[
|j, m\rangle = (-1)^{j+m} \frac{(j - m)!}{(j + m)!} v_{j+m}.
\]

(1.7)

The notation comes from the “bras” and “kets” formalism of Dirac in quantum mechanics. In the basis \(|j, m\rangle\),

\[
D^j \begin{cases} 
J_3|j, m\rangle = m|j, m\rangle, \\
J_+|j, m\rangle = \sqrt{(j - m)(j + m + 1)}|j, m + 1\rangle, \\
J_-|j, m\rangle = \sqrt{(j + m)(j - m + 1)}|j, m - 1\rangle.
\end{cases}
\]

(1.8)

Hence

\[
J_\pm|j, m\rangle = \sqrt{j(j + 1) - m(m \pm 1)}|j, m \pm 1\rangle.
\]

(1.9)
1.2 The Casimir Operator

In each representation space \((E, R)\) of \(\mathfrak{su}(2, \mathbb{C})\), we can consider the operator \((R(J_1))^2 + (R(J_2))^2 + (R(J_3))^2\), which we write in shorthand:

\[
J^2 = J_1^2 + J_2^2 + J_3^2.
\] (1.10)

Because \(J_+ J_- = (J_1 + i J_2)(J_1 - i J_2) = J_1^2 + J_2^2 - i [J_1, J_2] = J_1^2 + J_2^2 + J_3\), we have

\[
J^2 = J_+ J_- + J_3(J_3 - I) = J_- J_+ + J_3(J_3 + I).
\]

It is clear that if \(R = D^j\), each vector \(|j, m\rangle\) is an eigenvector of \(J^2\). More precisely, we find from (1.8) and (1.9) that

\[
J^2 |j, m\rangle = j(j + 1) |j, m\rangle.
\]

Thus we see that, in the representation \(D^j\), not only is each vector \(|j, m\rangle\) an eigenvector of \(J^2\), but in fact \(J^2\) acts as the multiple of the identity \(j(j + 1)I\). The operator \(J^2\) is called the Casimir operator of the representation \(D^j\).

1.3 Hermitian Nature of the Operators \(J_3\) and \(J^2\)

We shall show that the operators \(J_3\) and \(J^2\) in the representation \((E^j, D^j)\) of \(\mathfrak{sl}(2, \mathbb{C})\) are Hermitian with respect to a well-chosen scalar product on \(E^j\). We define the scalar product on \(E^j\) by requiring that \(|j, m\rangle\) be an orthonormal basis. We denote by \(X^*\) the adjoint of a matrix \(X\), i.e., \(X^* = t^X\). Then

**Proposition 1.2.**

\[
(J_+)^* = J_-,
\]

\[
(J_-)^* = J_+,
\]

\[
(J_3)^* = J_3,
\]

\[
(J^2)^* = J^2.
\]

**Proof.** We use the basis

\[
(|j, -j\rangle, |j, -j + 1\rangle, \ldots, |j, j - 1\rangle, |j, j\rangle),
\]

in the given order.

- The matrix of \(J_3\) in the basis above is \(
\begin{pmatrix}
-j \\
0 \\
\vdots \\
0 \\
\end{pmatrix}
\)

  ; thus \(J_3\) is real and symmetric, thus Hermitian (self-adjoint).

- The matrix of \(J_+\) is

\[
\begin{pmatrix}
0 & 0 & 0 \\
\sqrt{2j} & 0 & 0 \\
0 & \sqrt{2(2j - 1)} & 0 \\
0 & 0 & \sqrt{2(2j - 1)} \\
0 & 0 & 0 \\
\sqrt{2j} & 0 & 0 \\
0 & \sqrt{2(2j - 1)} & 0 \\
\end{pmatrix}
\]
The matrix of $J_-$ is
\[
\begin{pmatrix}
0 & \sqrt{2j} \\
0 & 0 & \sqrt{2(2j-1)} \\
0 & 0 & 0 & \ddots & \ddots & \ddots \\
0 & 0 & & \sqrt{2(2j-1)} & 0 & \sqrt{2j} \\
0 & 0 & & & 0 & \sqrt{2j}
\end{pmatrix}
\]

We have $(J_-)_{m+1,m} = \sqrt{j(j+1)} - m(m+1) = (J_+)_{m,m+1}$. Thus the matrices of $J_+$ and $J_-$ are real and are transposes of one another. Furthermore,
\[
(J^2)^* = J_-^* J_+^* + J_3(J_3 - I) = J_+ J_- + J_3(J_3 - I) = J^2.
\]
which proves the proposition.

In quantum physics, the Hermitian operators $J_3$ and $J^2$ are observables that correspond, respectively, to the component along the $z$-axis of the angular momentum and the square of its norm.

By restricting the representation $D^j$ to the real form $\mathfrak{su}(2)$ of $\mathfrak{sl}(2, \mathbb{C})$, we obtain a representation of $\mathfrak{su}(2)$, which we shall denote by the same symbol, $D^j$.

Because $J_3 = i\xi_3$, we deduce from Proposition 1.2 that
\[
D^j(\xi_3)^* = -D^j(\xi_3).
\]
Because $J_\pm = i\xi_1 \mp \xi_2$, we have
\[
\xi_1 = -\frac{i}{2}(J_+ + J_-), \quad \xi_2 = \frac{1}{2}(J_- - J_+),
\]
whence
\[
D^j(\xi_1)^* = -D^j(\xi_1), \quad D^j(\xi_2)^* = -D^j(\xi_2).
\]
As a consequence, for every $X \in \mathfrak{su}(2)$, $D^j(X)^* = -D^j(X)$. We thus have proved the following proposition.

**Proposition 1.3.** The operators of the representation $D^j$ of $\mathfrak{su}(2)$ are anti-Hermitian for the scalar product on $E^j$ defined by the condition that $|j, m\rangle$ be an orthonormal basis.

Thus, denoting this scalar product by $( \ | \ )$, we have
\[
(D^j(X)x_1 \ | \ x_2) = -(x_1 \ | \ D^j(X)x_2)
\]
for every $X \in \mathfrak{su}(2)$ and for every $x_1, x_2 \in E^j$. The matrix of $D^j(X)$ in the basis $|j, m\rangle$ is anti-Hermitian.
2 Representations of SU(2)

2.1 The Representations $D^j$

We shall study representations $D^j$ of SU(2), show that they have as differentials $D D^j$ the representations $D^j$ of $\mathfrak{su}(2)$ studied above, and show that these are the only irreducible representations of SU(2).

The group $\text{SL}(2, \mathbb{C})$ acts on $\mathbb{C}^2$ by the fundamental representation, so that

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} z_1 \\ z_2 \end{pmatrix} = \begin{pmatrix} az_1 + bz_2 \\ cz_1 + dz_2 \end{pmatrix}.
\]

As we have seen in Section 3.5 of Chapter 2, it is natural to make $\text{SL}(2, \mathbb{C})$ act on the space of functions from $\mathbb{C}^2$ to the complex numbers by

\[
\rho(g)f = f \circ g^{-1},
\]

for each function $f$ on $\mathbb{C}^2$. Thus one defines a representation of $\text{SL}(2, \mathbb{C})$. (Here “representation” means only that $\rho(gg') = \rho(g) \circ \rho(g')$ if $g$ and $g' \in \text{SL}(2, \mathbb{C})$.)

If $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ has determinant 1, then $g^{-1} = \begin{pmatrix} \bar{d} & -\bar{b} \\ -\bar{c} & \bar{a} \end{pmatrix}$; thus explicitly,

\[
(\rho(g)f)(z_1, z_2) = f(dz_1 - bz_2, -cz_1 + az_2). \tag{2.1}
\]

Let $V^j$ be the vector space of homogeneous polynomials with complex coefficients in two variables, $(z_1, z_2)$, of degree $2j$, where $j \in \frac{1}{2} \mathbb{N}$. This complex vector space is of dimension $2j + 1$. A basis is

\[
z_2^{2j}, z_1z_2^{2j-1}, \ldots, z_1^{j+m}z_2^{-m}, \ldots, z_2^j, -j \leq m \leq j.
\]

For example, these bases are

- if $j = \frac{1}{2}$, $z_2, z_1$,
- if $j = 1$, $z_2^2, z_1z_2, z_1^2$,
- if $j = \frac{3}{2}$, $z_2^3, z_1z_2^2, z_1^2z_2, z_1^3$.

Clearly, $V^j$ is invariant under the representation $\rho$ of SU(2). Now we shall study the representation $D^j$ of SU(2) on $V^j$ obtained by restriction.

We introduce the notation

\[
f_m^j(z_1, z_2) = z_1^{j+m}z_2^{-m}.
\]
Action of diagonal matrices in SU(2). In the representation $D^j$, the diagonal matrices of SU(2) act in a simple way on $V^j$. We set

$$g_t = \begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix} = \exp(tK) = \exp(2t\xi_3), \quad \text{where} \quad \xi_3 = \frac{1}{2} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}.$$

Then

$$(D^j(g_t)f_m^j)(z_1, z_2) = f_m^j(e^{-it}z_1, e^{it}z_2) = e^{-2imt}f_m^j(z_1, z_2),$$

and so

$$D^j(g_t)f_m^j = e^{-2imt}f_m^j.$$

Each $f_m^j$ is thus an eigenvector of $D^j(g_t)$ for the eigenvalue $e^{-2imt}$.

Calculation of the differential of $D^j$. Let $X = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \mathfrak{sl}(2, \mathbb{C})$ and

$$g(t) = \exp(tX) = \begin{pmatrix} a(t) & b(t) \\ c(t) & d(t) \end{pmatrix}.$$  

Then $g(0) = I$ and $g'(0) = X$, and thus $a(0) = d(0) = 1$, $b(0) = c(0) = 0$, and

$$a'(0) = \alpha, \quad b'(0) = \beta, \quad c'(0) = \gamma, \quad d'(0) = \delta.$$

Thus, for every polynomial $f$ in two variables,

$$((D\rho)(-X)f)(z_1, z_2) = \frac{d}{dt}(\rho(g(t)^{-1})f)(z_1, z_2)|_{t=0} = \frac{d}{dt}(f \circ g(t))(z_1, z_2)|_{t=0}$$

$$= (\alpha z_1 + \beta z_2)\partial_1 f(z_1, z_2) + (\gamma z_1 + \delta z_2)\partial_2 f(z_1, z_2).$$

Thus

$$((D\rho)(\xi_3)f)(z_1, z_2) = -\frac{i}{2}(z_1\partial_1 f - z_2\partial_2 f),$$

$$((D\rho)(\xi_1)f)(z_1, z_2) = -\frac{i}{2}(z_2\partial_1 f + z_1\partial_2 f),$$

$$((D\rho)(\xi_2)f)(z_1, z_2) = \frac{1}{2}(z_2\partial_1 f - z_1\partial_2 f).$$

Therefore we obtain

$$(D\rho)(J_3) = i(D\rho)(\xi_3) = \frac{1}{2}(z_1\partial_1 - z_2\partial_2),$$

$$(D\rho)(J_+) = i(D\rho)(\xi_1) - (D\rho)(\xi_2) = z_1\partial_2,$$

$$(D\rho)(J_-) = i(D\rho)(\xi_1) + (D\rho)(\xi_2) = z_2\partial_1.$$  

We shall study the action $D\rho$ restricted to $V^j$. It suffices to determine the value of the operators $(DD^j)(\xi_k)$, for $k = 1, 2, 3$, or $(DD^j)(J_3), (DD^j)(J_+), (DD^j)(J_-)$, on the basis vectors $f_m^j, -j \leq m \leq j$, of $V^j$. It is clear that

$$(DD^j)(\xi_3)f_m^j = -imf_m^j.$$
Using
\[ \partial_1 f^j_m = (j + m)z_1^{j+m-1}z_2^{-m}, \quad \partial_2 f^j_m = (j - m)z_1^{j+m}z_2^{-m-1}, \]
we obtain
\begin{align*}
(DD^j)\xi_1 f^j_m &= -\frac{i}{2}((j + m)f^j_{m-1} + (j - m)f^j_{m+1}), \\
(DD^j)\xi_2 f^j_m &= \frac{1}{2}((j + m)f^j_{m-1} - (j - m)f^j_{m+1}),
\end{align*}
and the simple formulas
\begin{align*}
(DD^j)(J_3)f^j_m &= mf^j_m, \\
(DD^j)(J_+)f^j_m &= (j - m)f^j_{m+1}, \\
(DD^j)(J-)f^j_m &= (j + m)f^j_{m-1}.
\end{align*}

We set
\[ |j, m\rangle = \frac{1}{\sqrt{(j - m)!(j + m)!}} f^j_m. \]

We have then
\[ DD^j \begin{cases} 
J_3 |j, m\rangle = m |j, m\rangle, \\
J_+ |j, m\rangle = \sqrt{(j - m)(j + m + 1)} |j, m + 1\rangle, \\
J_- |j, m\rangle = \sqrt{(j + m)(j - m + 1)} |j, m - 1\rangle.
\end{cases} \]

We deduce immediately from these formulas that the differential $DD^j$ of the representation $(V^j, D^j)$ of SU(2) is equivalent to the representation $D^j$ of the Lie algebra $\mathfrak{su}(2)$, because they are the restrictions of the same representation of $\mathfrak{sl}(2, \mathbb{C})$. We thus have proved the following proposition.

**Proposition 2.1.** The differential of the representation $D^j$ of SU(2) can be identified with the representation $D^j$ of $\mathfrak{su}(2)$.

From now on, we shall identify the support $V^j$ of $DD^j$ with the support $E^j$ of $D^j$.

**Proposition 2.2.** For each $j \in \mathbb{N}$, the representation $(V^j, D^j)$ of SU(2) is unitary for the scalar product on $V^j$ defined by requiring that $|j, m\rangle$ be an orthonormal basis.

**Proof.** In light of Theorem 7.6 of Chapter 4, this result is the consequence of Propositions 1.3 and 2.1, and of the fact that SU(2) is connected. \(\Box\)

For each $g \in \text{SU}(2)$, the matrix of $D^j(g)$ in the basis $|j, m\rangle$ is thus unitary.

**Proposition 2.3.** For each $j$, integer or half-integer, $(V^j, D^j)$ is an irreducible representation of SU(2) of dimension $2j + 1$. 
Proof. By Theorem 7.6 of Chapter 4, the proposition follows from the fact that the differential of $D^j$ is an irreducible representation. (If $V$ is a vector subspace of $V^j$ invariant under $D^j$, it is invariant under $DD^j$, and thus $V$ is trivial.) □

Corollary 2.4. Every irreducible representation of $SU(2)$ is equivalent to one of the representations $(V^j, D^j)$, $j \in \frac{1}{2} \mathbb{N}$.

Proof. Because the group $SU(2)$ is compact, we know, by Theorem 4.3 of Chapter 3, that every irreducible representation of $SU(2)$ is finite-dimensional. We have seen that each finite-dimensional irreducible representation of $su(2)$ is one of the $D^j$, $j \in \frac{1}{2} \mathbb{N}$. Because $SU(2)$ is connected, the result follows. □

2.2 Characters of the Representations $D^j$

By definition, for $j \in \frac{1}{2} \mathbb{N}$, $\chi_j(t) = \chi_{D^j}(t) = \sum_{m=-j}^{j} e^{2imt}$. Therefore, for every $t \in (0, \pi)$,

$$\chi_j(t) = \frac{\sin(2j + 1)t}{\sin t}.$$  

We have $\chi_j(0) = 2j + 1$, which is the dimension of the representation, and $\chi_j(\pi) = (-1)^{2j}(2j + 1)$.

Character of $D^{j_1} \otimes D^{j_2}$. One can express $\chi_j(t)$ as a function of $X = e^{2it}$, for $j \in \frac{1}{2} \mathbb{N}$. If $t \neq 0$ and $t \neq \pi$,

$$\chi_j(t) = \sum_{m=-j}^{j} X^m = \frac{X^{j+1} - X^{-j}}{X - 1}.$$  

Let $j_1$ and $j_2 \in \frac{1}{2} \mathbb{N}$. We have

$$\chi_{j_1}(t)\chi_{j_2}(t) = \left(\sum_{m=-j_1}^{j_1} X^m\right)\left(\frac{X^{j_2+1} - X^{-j_2}}{X - 1}\right)$$

$$= \frac{1}{X - 1} \left(\sum_{m=-j_1}^{j_1} X^{m+j_2+1} - \sum_{m=-j_1}^{j_1} X^{m-j_2}\right).$$

We set $m = j_1 - k$ in the first sum and $m = k - j_1$ in the second. We obtain

$$\chi_{j_1}(t)\chi_{j_2}(t) = \frac{1}{X - 1} \left(\sum_{k=0}^{2j_1} X^{j_1+j_2+1-k} - \sum_{k=0}^{2j_1} X^{-j_1-j_2+k}\right).$$

Suppose $j_1 \leq j_2$. Then $0 \leq k \leq 2j_1$ implies $j_1 + j_2 - k \geq 0$, and thus

$$\chi_{j_1}(t)\chi_{j_2}(t) = \sum_{k=0}^{2j_1} \chi_{j_1+j_2-k}(t) = \chi_{j_1+j_2}(t) + \chi_{j_1+j_2-1}(t) + \cdots + \chi_{j_2-j_1}(t).$$
For \( t = 0 \), the left-hand side is \( \chi_{j_1}(t)\chi_{j_2}(t) = (2j_1 + 1)(2j_2 + 1) \). On the right-hand side, there are \( 2j_1 + 1 \) terms whose sum is
\[
\sum_{k=0}^{2j_1} \chi_{j_2-j_1+k}(0) = \sum_{k=0}^{2j_1} (2(j_1 + j_2) + 1 - 2k) = (2j_1 + 1)(2(j_1 + j_2) + 1) - 2j_1(2j_1 + 1) = (2j_1 + 1)(2j_2 + 1).
\]
The formula thus holds in this case. The proof for \( t = \pi \) is analogous. We have thus proved the formula
\[
\chi_{j_1}\chi_{j_2} = \chi_{|j_2-j_1|} + \chi_{|j_2-j_1|+1} + \cdots + \chi_{j_1+j_2}.
\] (2.3)

From (2.3) and from equation (2.2) of Chapter 2, we deduce the decomposition of the tensor product \( D^{j_1} \otimes D^{j_2} \) into a direct sum of irreducible representations, called the Clebsch–Gordan formula:
\[
D^{j_1} \otimes D^{j_2} = D^{|j_2-j_1|} \oplus D^{|j_2-j_1|+1} \oplus \cdots \oplus D^{j_1+j_2}.
\] (2.4)

### 3 Representations of SO(3)

We recall the existence of the surjective morphism \( \varphi \) from SU(2) onto SO(3), with kernel \{I, -I\}, studied in Section 2.3 of Chapter 5. If \((E, \rho)\) is a representation of SU(2), then \( \rho \) factors through the projection \( \varphi \) if and only if \( \rho(-I) = \rho(I) = \text{Id}_E \). (3.5)

If \( \rho \) factors through \( \varphi \) as \( \sigma \circ \varphi \), where \( \sigma : \text{SO}(3) \to \text{GL}(E) \), then \( \sigma \) is a representation of SO(3), and \( \rho \) is irreducible if and only if \( \sigma \) is irreducible. The representation \( D^j \) of SU(2) satisfies the condition (3.5) if and only if \( j \) is integer. In fact \(-I = g_\pi \) and \( D^j(g_\pi)f_m^j = e^{-2im\pi}f_m^j \), where the scalar factor is 1 if and only if \( m \) is integer, thus if and only if \( j \) is integer. Thus we see that the representations obtained by factorization of \( D^0, D^1, D^2, \ldots, D^j, \ldots \), where \( j \) is integer, are irreducible representations of SO(3). We denote these representations of SO(3) by \( D^j \) or even \( D^j \), by abuse of notation. Because the Lie group SO(3) is connected, we can conclude the following:

**Theorem 3.1.** Every irreducible representation of SO(3) is equivalent to one of the representations \((V^j, D^j)\), \( j \in \mathbb{N} \).

### References

One can find the results concerning the representations of SU(2) and of SO(3) in many sources, including Fulton–Harris (1991), Sternberg (1994), Talman (1969), and Gilmore (1974), since they are fundamental in mathematics and in physics.

Alfred Clebsch (1833–1872) and Paul Gordan (1837–1912) developed the theory of invariants. The “Clebsch–Gordan formula” is a modern group-theoretic interpretation of the finite series expansion for the invariants of binary forms (polynomials in two variables), which they derived independently in 1872 and 1871, respectively.

Hendrik Casimir (1909–2000) was led to the definition of the operator that bears his name in the early 1930s after defending his thesis on the quantum mechanics of the rigid body and finding inspiration in Weyl (1931).

Exercises

**Exercise 6.1 Equivalent representations.**
We set, for \( g \in \text{SU}(2) \) and for each complex-valued function \( f \) on \( \mathbb{C}^2 \),
\[
\tilde{\rho}(g)f = f \circ \bar{g}^{-1}.
\]
Show that \( \tilde{\rho} : \text{SU}(2) \to \text{GL}(V^j) \) is a representation of \( \text{SU}(2) \) equivalent to \( D^j \).

**Exercise 6.2 The representations \( D^{\frac{1}{2}} \) and \( D^1 \).**
(a) Write the matrices of \( J_3, J_+ \), and \( J_- \) in the basis \( f^i_{lm} \) for the representations \( D^{\frac{1}{2}} \) and \( D^1 \). Same question for \( \xi_1, \xi_2, \xi_3 \).
(b) Is the representation \( D^{\frac{1}{2}} \) equivalent to the fundamental representation of \( \text{SU}(2) \) on \( \mathbb{C}^2 \)? Is the representation \( D^1 \) equivalent to the complexification of the fundamental representation of \( \text{SO}(3) \) on \( \mathbb{R}^3 \)?
(c) Decompose \( D^{1/2} \otimes D^{1/2}, D^1 \otimes D^1, D^{1/2} \otimes D^1, \) and \( D^{1/2} \otimes D^{1/2} \otimes D^{1/2} \) into direct sums of irreducible representations.

**Exercise 6.3 Differential operators on polynomials.**
(a) Using the Euler identity for the homogeneous polynomials of degree \( 2j \), show that
\[
(DD^j)(J_3)f = (j - z_1 \partial_1)f = (z_2 \partial_2 + j)f.
\]
(b) Express \( J_+ J_- + J_- J_+ \), \( (J_3)^2 \) and \( J^2 \) as differential operators of order less than or equal to 2 on the homogeneous polynomials of two variables of degree \( 2j \).

**Exercise 6.4 Clebsch–Gordan coefficients.**
In the tensor product \( V^{j_1} \otimes V^{j_2} \), we consider the two orthonormal bases
\[
|j_1, m_1 \rangle \otimes |j_2, m_2 \rangle, \quad -j_1 \leq m_1 \leq j_1, \quad -j_2 \leq m_2 \leq j_2,
\]
and
\[
|J, M \rangle, \quad |j_1 - j_2| \leq J \leq j_1 + j_2, \quad -J \leq M \leq J.
\]
The Clebsch–Gordan coefficients are the coefficients $C(J, M, j_1, m_1, j_2, m_2)$ of the change-of-basis matrix

$$|J, M\rangle = \sum_{m_1, m_2} C(J, M, j_1, m_1, j_2, m_2) |j_1, m_1\rangle \otimes |j_2, m_2\rangle .$$

Calculate the Clebsch–Gordan coefficients in the case of $V^{1/2} \otimes V^{1/2}$ and of $V^{1/2} \otimes V^1$.

**Exercise 6.5** Restriction to SO(2) of the representations $D^j$.

(a) Find the irreducible representations of the group SO(2).
(b) Find the character of the representation $D^j$ of SO(3), for $j \in \mathbb{N}$.
(c) Decompose the restriction to SO(2) of the representation $D^j$ of SO(3), for $j \in \mathbb{N}$, into a direct sum of irreducible representations.
(d) Identify $D^1$ with the complexification of the fundamental representation of SO(3), and find a basis of $\mathbb{C}^3$ adapted to the decomposition, of the restriction of $D^1$ to SO(2). Is the restriction to SO(2) of the fundamental representation of SO(3) reducible?

**Exercise 6.6** Matrix coefficients of $D^j$.

We set, for $\theta \in [0, \pi]$,

$$d^j(\theta) = D^j(\exp(\theta \xi_1)).$$

Calculate the matrix coefficients $d^1_{00}, d^1_{10},$ and $d^1_{-1,0}$ in the orthonormal basis $|j, m\rangle$.

**Exercise 6.7** Orthogonality of characters.

(a) Find the value of the integral

$$\int_0^{2\pi} \frac{\sin(j_1 + \frac{1}{2})t}{\sin \frac{t}{2}} \frac{\sin(j_2 + \frac{1}{2})t}{\sin \frac{t}{2}} \frac{\sin(j + \frac{1}{2})t}{\sin \frac{t}{2}} \, dt$$

in terms of the values of $j_1, j_2, j \in \mathbb{N}$.
(b) Same question for $j_1, j_2, j \in \frac{1}{2} \mathbb{N}$. 
Chapter 7

Spherical Harmonics

Spherical harmonics play an important role in electrodynamics and in quantum mechanics. We shall show how they appear in the representation theory of the rotation group \( \text{SO}(3) \). Each irreducible representation of \( \text{SO}(3) \) can be realized in a finite-dimensional Hilbert space of functions on the sphere, the restrictions of harmonic homogeneous polynomials of a given degree, and this representation is unitary. We shall determine an orthonormal basis of this space that is transformed in a simple way under the action of the group of rotations: the elements of such a basis are simultaneous eigenfunctions for the operators \( J_3 \) and \( J^2 \), defined below. The functions thus defined on the sphere are called spherical harmonics.

1 Review of \( L^2(S^2) \)

We denote by \( S^2 \) the unit sphere in \( \mathbb{R}^3 \),

\[ S^2 = \{(x_1, x_2, x_3) \in \mathbb{R}^3 \mid (x_1)^2 + (x_2)^2 + (x_3)^2 = 1\}. \]

We introduce spherical coordinates \((r, \theta, \phi)\) on \( \mathbb{R}^3 \), \( r \geq 0, \theta \in [0, \pi], \phi \in [0, 2\pi) \), such that

\[ x_1 = r \sin \theta \cos \phi, \quad x_2 = r \sin \theta \sin \phi, \quad x_3 = r \cos \theta. \]

The angle \( \phi \) is the longitude and \( \theta \) is the colatitude. On \( \mathbb{R}^3 \) minus the axis \( Ox_3 \) \((r > 0 \text{ and } 0 < \theta < \pi)\), the passage from Cartesian coordinates to spherical coordinates is smooth. The volume element of \( \mathbb{R}^3 \) is then \( r^2 \sin \theta \, dr \, d\theta \, d\phi \), and the surface area element on the unit sphere is

\[ d\mu = \frac{1}{4\pi} \sin \theta \, d\theta \, d\phi. \]

We denote by \( L^2(S^2) \) the separable Hilbert space of (equivalence classes of) complex functions on \( S^2 \) that are square-integrable for the scalar product

\[ (f_1 | f_2) = \frac{1}{4\pi} \int_{S^2} f_1(\theta, \phi) f_2(\theta, \phi) \sin \theta \, d\theta \, d\phi. \]
In spherical coordinates, the Laplacian $\Delta = (\partial/\partial x_1)^2 + (\partial/\partial x_2)^2 + (\partial/\partial x_3)^2$ can be written

$$\Delta = \frac{\partial^2}{\partial r^2} + \frac{2}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \Delta_{S^2},$$

where $\Delta_{S^2}$ is the spherical Laplacian,

$$\Delta_{S^2} = \frac{\partial^2}{\partial \theta^2} + \cot \theta \frac{\partial}{\partial \theta} + \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \phi^2}.$$ 

## 2 Harmonic Polynomials

### 2.1 Representations of Groups on Function Spaces

We shall make use of the important fact, stated in Section 3.1 of Chapter 2, that each group of transformations of a space can be represented on the vector space of complex-valued functions on that space. If $f$ is a function on $\mathbb{R}^3$, and if $g \in \text{SO}(3)$, we set, for $x \in \mathbb{R}^3$,

$$(g \cdot f)(x) = f(g^{-1}x),$$

and this defines a representation of $\text{SO}(3)$ on the vector space of functions on $\mathbb{R}^3$. (This turns out to be an infinite-dimensional representation. Here we talk of representation from the algebraic point of view only, without insisting on continuity.) We shall denote this representation by $\sigma$, defined by

$$\sigma(g)f = g \cdot f.$$ 

By abuse of language, we denote its restriction to certain subspaces of functions also by $\sigma$.

We introduce the harmonic polynomials and show that, by restricting $\sigma$ to spaces of harmonic polynomials, we obtain all the irreducible representations of $\text{SO}(3)$, which were determined in Chapter 6.

### 2.2 Spaces of Harmonic Polynomials

**Definition 2.1.** We call a function $f$ of class $C^2$ harmonic on $\mathbb{R}^3$ if

$$\Delta f = 0.$$ 

For any nonnegative integer $\ell$ we denote by $P^{(\ell)}$ the vector space of homogeneous polynomials of degree $\ell$ with complex coefficients on $\mathbb{R}^3$. We then consider the vector subspace of $P^{(\ell)}$ consisting of harmonic polynomials, i.e., polynomials with vanishing Laplacian, which we denote by $H^{(\ell)}$.

**Lemma 2.2.** The vector space $H^{(\ell)}$ is of dimension $2\ell + 1$. 

Proof. First we calculate the dimension of the vector space $P(\ell)$. A homogeneous polynomial of degree $\ell$ on $\mathbb{R}^3$ is determined by $\ell+1$ homogeneous polynomials in two variables, of respective degrees $0, 1, \ldots, \ell$. Because the vector space of homogeneous polynomials in two variables of degree $k$ is of dimension $k+1$, we obtain

$$\dim P(\ell) = 1 + 2 + \cdots + (\ell + 1) = \frac{(\ell + 1)(\ell + 2)}{2}.$$ 

We observe next that the operator $\Delta$ sends $P(\ell)$ into $P(\ell-2)$. Let us show that the linear map $\Delta : P(\ell) \to P(\ell-2)$ is surjective. First we observe that for every $q_3 \in \mathbb{N}$, $x_3^{q_3}$ belongs to the image of $\Delta$, because $\Delta(x_3^{q_3+2}) = (q_3 + 2)(q_3 + 1)x_3^{q_3}$. Similarly, one can easily see that $x_1x_3^{q_3}$ and $x_2x_3^{q_3}$ are in $\text{Im } \Delta$. The formula

$$\Delta(x_1^{q_1}x_2^{q_2}x_3^{q_3}) = q_1(q_1 - 1)x_1^{q_1-2}x_2^{q_2}x_3^{q_3} + q_2(q_2 - 1)x_1^{q_1}x_2^{q_2-2}x_3^{q_3} + q_3(q_3 - 1)x_1^{q_1}x_2^{q_2}x_3^{q_3-2},$$

which holds for every $q_1, q_2, q_3 \in \mathbb{N}$, shows that if the property $x_1^{q_1}x_2^{q_2}x_3^{q_3} \in \text{Im } \Delta$ is true for $q_1 + q_2 = q - 2$, it is true for $q_1 + q_2 = q$. Since this property is true for $q = 0$ and for $q = 1$, the surjectivity of the linear map $\Delta : P(\ell) \to P(\ell-2)$ is thus proved by induction on $q$. Consequently, $\dim H(\ell) = \dim P(\ell) - \dim P(\ell-2) = 2\ell + 1$. $\square$

2.3 Representations of $\text{SO}(3)$ on Spaces of Harmonic Polynomials

Let us prove that $\text{SO}(3)$ acts on $H(\ell)$. It is clear that if $P \in P(\ell)$ and if $g \in \text{SO}(3)$, then $\sigma(g)P = g \cdot P$ is still a homogeneous polynomial of degree $\ell$.

Proposition 2.3. The subspace $H(\ell)$ of $P(\ell)$ is invariant under $\sigma$.

Proof. Let $f$ be a function of three variables of class $C^2$ and let $g$ be in $\text{SO}(3)$. We denote by $(A_{ij})$, $i, j = 1, 2, 3$, the matrix of $g$, and by $y_i$ the components of $y = g(x)$, for $x \in \mathbb{R}^3$. We have

$$\frac{\partial}{\partial x_i} (f \circ g)(x) = \sum_{j=1}^{3} A_{ji} \frac{\partial f}{\partial y_j}(y).$$

Hence

$$(\Delta(f \circ g))(x) = \sum_{i,j,k=1}^{3} A_{ij}A_{ki} \frac{\partial^2 f}{\partial y_j \partial y_k}(y).$$

Because $(A_{ij})$ is an orthogonal matrix, we obtain

$$(\Delta(f \circ g))(x) = \sum_{j=1}^{3} \frac{\partial^2 f}{\partial y_j^2}(y) = (\Delta f)(g(x)), $$

that is, $\Delta(f \circ g) = (\Delta f) \circ g$. Consequently, if $P$ is a harmonic polynomial, then for every $g \in \text{SO}(3)$, the polynomial $\sigma(g)P = g \cdot P = P \circ g^{-1}$ is also harmonic. $\square$
On the other hand, for a given homogeneous polynomial $P$, the coefficients of the polynomials $g \cdot P$ depend continuously on the coefficients of the matrix $g \in \text{SO}(3)$. Thus we can state the following.

**Proposition 2.4.** By restricting $\sigma$ to $H^{(\ell)}$, we obtain, for each $\ell \in \mathbb{N}$, a representation $(H^{(\ell)}, \sigma^\ell)$ of $\text{SO}(3)$ of dimension $2\ell + 1$.

We shall show that the representation $\sigma^\ell$ of $\text{SO}(3)$ on $H^{(\ell)}$ is equivalent to the representation $D^\ell$ defined in Section 3 of Chapter 6. For this, we shall use the following lemma.

**Lemma 2.5.** For $\ell \in \mathbb{N}$, let $(V, \rho)$ be a representation of dimension $2\ell + 1$ of $\text{SU}(2)$. If $e^{2i\ell \theta}$ or $e^{-2i\ell \theta}$ is an eigenvalue of $\rho(g_\theta)$, where $g_\theta = \begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{pmatrix}$, then $\rho$ is equivalent to $D^\ell$.

**Proof.** We can decompose the given representation into a direct sum of irreducible representations,

$$
\rho = \bigoplus_{j=0}^{j_0} m_j D^j,
$$

and since $\dim V = 2\ell + 1$, it follows that $j_0 \leq \ell$. If we had $j_0 < \ell$, all the eigenvalues of $\rho(g_\theta)$ would be of the form $e^{2im\theta}$, with $|m| < \ell$. Thus, one of the $D^j$ in the direct sum is equal to $D^\ell$. The condition on the dimension of the representation then implies that $\rho = D^\ell$.

We immediately deduce from this lemma that a $(2\ell + 1)$-dimensional representation $(V, \sigma)$ of $\text{SO}(3)$, where $\ell \in \mathbb{N}$, is equivalent to $D^\ell$ if and only if $e^{2i\ell \theta}$ or $e^{-2i\ell \theta}$ is an eigenvalue of $\sigma(\varphi(g_\theta))$. Here $\varphi$ is the morphism of $\text{SU}(2)$ onto $\text{SO}(3)$ defined in Section 2.3 of Chapter 5.

**Proposition 2.6.** The representation $\sigma^\ell$ of $\text{SO}(3)$ on $H^{(\ell)}$ is equivalent to the representation $D^\ell$.

**Proof.** The polynomial $p_\ell = (x_1 + ix_2)^\ell$ belongs to $P^{(\ell)}$. We can easily see that it is harmonic. Furthermore, in the representation $\sigma^\ell$ of $\text{SO}(3)$ on $H^{(\ell)}$, it is an eigenfunction of $\varphi(g_\theta)$ for the eigenvalue $e^{-2i\ell \theta}$, because

$$
\varphi(g_\theta) = \varphi(\exp2\theta \xi_3) = \text{Rot}(e_3, 2\theta) = \begin{pmatrix}
\cos 2\theta & -\sin 2\theta & 0 \\
\sin 2\theta & \cos 2\theta & 0 \\
0 & 0 & 1
\end{pmatrix}
$$

and consequently,

$$
(\varphi(g_\theta)) \cdot p_\ell = e^{-2i\ell \theta} p_\ell.
$$

The lemma then gives the desired result.

**Proposition 2.7.** For each $\ell \geq 2$,

$$
P^{(\ell)} = H^{(\ell)} \oplus r^2 P^{(\ell-2)}.
$$
Proof. The sum of the dimensions of the subspaces $H(\ell)$ and $r^2 P(\ell-2)$ of $P(\ell)$ is equal to the dimension of $P(\ell)$. Let us show that their intersection is trivial. If $P \in P(\ell)$, then with the help of the Euler identity $x_1 \frac{\partial P}{\partial x_1} + x_2 \frac{\partial P}{\partial x_2} + x_3 \frac{\partial P}{\partial x_3} = \ell P$, we establish, for every integer $k \geq 0$, the formula

$$\Delta(r^{2k} P) = 2k(2\ell + 2k + 1) r^{2k-2} P + r^{2k} \Delta P.$$  

For $P \in H(\ell)$, let $k$ be the largest integer such that there exists a polynomial $Q \in P(\ell-2k)$ satisfying $P = r^{2k} Q$. We thus have $0 = 2k(2\ell - 2k + 1) r^{2k-2} Q + r^{2k} \Delta Q$. We must have $k = 0$, since if not, $Q$ would be divisible by $r^2$, which contradicts the hypothesis on $k$. 

We deduce from this proposition that

$$P(\ell) = H(\ell) \oplus r^2 H(\ell-2) \oplus \cdots,$$

(2.1)

where the last term is $r^\ell H(0)$ if $\ell$ is even, and $r^{\ell-1} H(1)$ if $\ell$ is odd.

3 Definition of Spherical Harmonics

A homogeneous polynomial on $\mathbb{R}^3$ is entirely determined by its restriction to the unit sphere $S^2$.

**Definition 3.1.** The functions on the sphere obtained by restriction of harmonic homogeneous polynomials are called spherical harmonics.

For each nonnegative integer $\ell$, the spherical harmonics of degree $\ell$ form a vector space $\tilde{H}(\ell)$ of dimension $2\ell + 1$ that is isomorphic to $H(\ell)$ and contained in the space of smooth functions on the sphere, itself contained in $L^2(S^2)$.

We observe first that by equation (2.1), the space of restrictions to the sphere of homogeneous polynomials of degree $\ell$ can be written

$$\tilde{P}(\ell) = \tilde{H}(\ell) \oplus \tilde{H}(\ell-2) \oplus \cdots,$$

(3.1)

where the last term is $\tilde{H}(0)$ if $\ell$ is even, and $\tilde{H}(1)$ if $\ell$ is odd.

3.1 Representations of SO(3) on Spaces of Spherical Harmonics

For each $\ell \in \mathbb{N}$, by the identification of $\tilde{H}(\ell)$ with $H(\ell)$, we obtain a representation, also denoted by $\sigma^\ell$, of SO(3) on the space of spherical harmonics of degree $\ell$. These representations are unitary, as one can easily see using the rotational invariance of the measure on $S^2$. In fact, for all functions $f_1$ and $f_2 \in L^2(S^2)$, and each $g \in SO(3)$, setting $\sigma(g)f = f \circ g^{-1}$ yields

$$\langle \sigma(g)f_1 | \sigma(g)f_2 \rangle = \int_{S^2} f_1(g^{-1}x) f_2(g^{-1}x) d\mu(x) = \int_{S^2} f_1(x) f_2(x) d\mu(x) = \langle f_1 | f_2 \rangle.$$  

We have already seen (see Chapter 6, Section 2.1) that when a Lie group is represented on a function space, the differential of the representation associated
to each element of the Lie algebra of the group is a differential operator on the functions (when these are differentiable). By Theorem 7.6 of Chapter 4, if the representation of the group is unitary, the representation of the Lie algebra is anti-Hermitian.

Let $\eta_1, \eta_2, \eta_3$ be the basis of the Lie algebra $\mathfrak{so}(3)$ of SO(3), introduced in Section 1.2 of Chapter 5. We see easily, by calculating $\frac{d}{dt} f(\exp(-t\eta_k)x)|_{t=0}$ for each $f \in C^\infty(\mathbb{R}^3)$, $x \in \mathbb{R}^3$ with components $x_1, x_2, x_3$, and $k = 1, 2, 3$, that the differential $D\sigma$ of the representation $\sigma$ of SO(3) on $C^\infty(\mathbb{R}^3)$ is such that

$$(D\sigma)\eta_1 = x_3 \frac{\partial}{\partial x_2} - x_2 \frac{\partial}{\partial x_3},$$

$$(D\sigma)\eta_2 = x_1 \frac{\partial}{\partial x_3} - x_3 \frac{\partial}{\partial x_1},$$

$$(D\sigma)\eta_3 = x_2 \frac{\partial}{\partial x_1} - x_1 \frac{\partial}{\partial x_2}.$$ 

By restriction, these formulas define the action of $\mathfrak{so}(3)$ on $P(\ell)$ and $H(\ell)$, and thus on $\tilde{H}(\ell)$. In spherical coordinates,

$$(D\sigma)\eta_1 = \sin \phi \frac{\partial}{\partial \theta} + \cos \phi \cot \theta \frac{\partial}{\partial \phi},$$

$$(D\sigma)\eta_2 = -\cos \phi \frac{\partial}{\partial \theta} + \sin \phi \cot \theta \frac{\partial}{\partial \phi},$$

$$(D\sigma)\eta_3 = -\frac{\partial}{\partial \phi}.$$ 

Each of these operators is anti-Hermitian for the scalar product of $L^2(S^2)$, since the operators associated to elements of the group SO(3) by $\sigma$ are unitary, and this fact can also be proved by a direct calculation. We introduce the operators

$$J_3 = -i \frac{\partial}{\partial \phi},$$

$$J_1 = i \left( \sin \phi \frac{\partial}{\partial \theta} + \cos \phi \cot \theta \frac{\partial}{\partial \phi} \right),$$

$$J_2 = i \left( -\cos \phi \frac{\partial}{\partial \theta} + \sin \phi \cot \theta \frac{\partial}{\partial \phi} \right),$$

which are thus Hermitian. We introduce also $J_{\pm} = J_1 \pm iJ_2$,

$$J_{\pm} = e^{\pm i\phi} \left( \pm \frac{\partial}{\partial \theta} + i \cot \theta \frac{\partial}{\partial \phi} \right).$$

While the operator $J_3$ is Hermitian, the operators $J_+$ and $J_-$ are adjoint to one another.

Remark. The notation is consistent with that of Chapter 5. The Hermitian operators $J_k$ are associated to the matrices $J_k = i\xi_k$ or $\hat{J}_k = i\eta_k$, while the operators $J_{\pm}$ are associated to $J_{\pm} = J_1 \pm iJ_2 = i\xi_1 \mp \xi_2$ or $\hat{J}_{\pm} = \hat{J}_1 \pm i\hat{J}_2 = i\eta_1 \mp \eta_2$. But to be perfectly rigorous, the operators we denote by $J_k$ are by definition $i(D\sigma)\eta_k$ rather than $(D\sigma)(i\eta_k)$, since the $i\eta_k$ do not belong to $\mathfrak{so}(3)$.
3.2 The Casimir Operator

Now we introduce the Casimir operator of the representation in question (see Section 1.2 of Chapter 6),

\[ J^2 = J_1^2 + J_2^2 + J_3^2 = J_+ J_- + J_3^2 - J_3, \]

with the notation as above. The operator \( J^2 \) is Hermitian, since \( J_3 \) as well as \( J_+ J_- \) are Hermitian.

A simple calculation shows that \( J^2 \) is equal to the negative of the spherical Laplacian,

\[ J^2 = -\Delta_{S^2}, \]

that is,

\[ \sum_{k=1}^{3} ((D\sigma)\eta_k)^2 = \Delta_{S^2}. \]

3.3 Eigenfunctions of the Casimir Operator

We can write for \( P \in P^{(\ell)} \),

\[ P(r, \theta, \phi) = r^\ell Y(\theta, \phi). \]

The condition \( \Delta P = 0 \) is equivalent to

\[ \Delta_{S^2} Y = -\ell(\ell + 1)Y. \]

Therefore, the numbers \(-\ell(\ell + 1)\), for nonnegative integer \( \ell \), are eigenvalues of the operator \( \Delta_{S^2} \), of multiplicity \( 2\ell + 1 \), since the corresponding eigenspace is \( \tilde{H}^{(\ell)} \). Thus,

\[ \Delta_{S^2} |_{\tilde{H}^{(\ell)}} = -\ell(\ell + 1)\text{Id}_{\tilde{H}^{(\ell)}}. \]

Theorem 3.2. The space \( L^2(S^2) \) is the Hilbert direct sum of the \( \tilde{H}^{(\ell)} \), for \( \ell \in \mathbb{N} \).

Proof. We show first that the \( \tilde{H}^{(\ell)} \) are pairwise orthogonal in \( L^2(S^2) \). This is the consequence of the fact that these are the eigenspaces of the operator \( \Delta_{S^2} \), which is Hermitian, as we have just shown.

Because the space of continuous functions on \( S^2 \) is dense in \( L^2(S^2) \), it suffices to show that each continuous function on \( S^2 \) is a uniform limit of sums of elements of the \( \tilde{H}^{(\ell)} \). By the Weierstrass theorem, we can approximate any continuous function on \( S^2 \) by the restriction of polynomials on \( \mathbb{R}^3 \). We then decompose the polynomials into sums of homogeneous polynomials, and in view of the decomposition (3.1), the proof is then complete. \( \square \)

We see that the space of square-integrable functions on the sphere decomposes into a Hilbert sum of eigenspaces of the spherical Laplacian, which are the spaces of spherical harmonics. Thus we can conclude as follows.
Corollary 3.3. The spectrum of the Casimir operator operating on the functions of class $C^2$ on the sphere is discrete, its eigenvalues are the integers $\ell(\ell + 1)$, $\ell \in \mathbb{N}$, and the associated eigenfunctions are the spherical harmonics of degree $\ell$.

Remark. The observables of quantum mechanics are Hermitian operators on the Hilbert space of states. As we observed in Chapter 6, the Hermitian operators $J_k$, $k = 1, 2, 3$, and $J^2$ have a physical interpretation: up to a factor of $\hbar$ ($\hbar = h/2\pi$, where $h$ is Planck’s constant), $J_1, J_2, J_3$ are the observables associated to the components of the angular momentum of a particle, and up to the factor $\hbar^2$, $J^2$ is the observable associated to the square of the norm of the angular momentum. Thus the numbers $\hbar^2 \ell(\ell + 1)$, for nonnegative integers $\ell$, are the eigenvalues of the square of the norm of the angular momentum.

3.4 Bases of Spaces of Spherical Harmonics

More particularly, we use the name spherical harmonics for the elements of an orthonormal basis $Y_{\ell}^m$, $-\ell \leq m \leq \ell$, of $\tilde{H}(\ell) \subset L^2(S^2)$, for each nonnegative integer $\ell$. Some authors seek to realize the orthonormalization condition according to the normalized scalar product on $L^2(S^2)$ introduced in Section 1, while others use the unnormalized scalar product defined by

$$\langle f_1 | f_2 \rangle = \int_0^\pi \int_0^{2\pi} f_1(\theta, \phi) f_2(\theta, \phi) \sin \theta \, d\theta \, d\phi.$$ 

We define the following functions, for $\ell \geq 0$. If $0 \leq m \leq \ell$, we set

$$Y_{\ell}^m(\theta, \phi) = \gamma_m Z_{\ell}^m(\theta) e^{im\phi},$$

where

$$Z_{\ell}^m(\theta) = \sin^m \theta Q_{\ell}^m(\cos \theta), \quad Q_{\ell}^m(x) = \frac{d^{\ell+m}}{dx^{\ell+m}}(1 - x^2)^{\ell},$$

and $\gamma_m$ is the real number

$$\gamma_m = \frac{(-1)^{\ell+m}}{\ell!} \frac{2\ell + 1}{4\pi} \sqrt{\frac{(\ell - m)!}{(\ell + m)!}}.$$

If $-\ell \leq m < 0$, we set

$$Y_{\ell}^m = (-1)^m Y_{-m}^{-\ell}.$$

Thus we define, for each $\ell \geq 0$, a family $Y_{\ell}^m$, $-\ell \leq m \leq \ell$, of $2\ell + 1$ functions on the sphere. We shall show that these functions are spherical harmonics in the preceding sense, and that they form an orthonormal basis of the space $\tilde{H}(\ell)$ for the unnormalized scalar product $\langle \cdot | \cdot \rangle$.

On the one hand, the functions $Y_{\ell}^m$ are eigenvectors of the operator $J_3 = -i \partial / \partial \phi$ with eigenvalue $m$,

$$J_3 Y_{\ell}^m = m Y_{\ell}^m.$$  \hfill (3.3)
On the other hand, the functions $Y^\ell_m$ satisfy the equations

$$J_+ Y^\ell_m = \sqrt{(\ell - m)(\ell + m + 1)} Y^\ell_{m+1}, \quad (3.4)$$

and

$$J_- Y^\ell_m = \sqrt{(\ell + m)(\ell - m + 1)} Y^\ell_{m-1}, \quad (3.5)$$

which we can easily verify by distinguishing the cases $m \geq 0$ and $m < 0$. Thus we see that the functions $Y^\ell_m$ are eigenvectors of $J^2 = -\Delta_{S^2}$ with eigenvalue $\ell(\ell + 1)$,

$$J^2 Y^\ell_m = \ell(\ell + 1) Y^\ell_m, \quad (3.6)$$

and we note that the eigenvalue does not depend on $m$. Each function $Y^\ell_m$ is thus seen to be a spherical harmonic. Because the operator $J_3$ is Hermitian, the functions $Y^\ell_m$ are pairwise orthogonal. These $2\ell + 1$ functions of $\tilde{H}^{(\ell)}$ thus form an orthogonal basis.

The functions $Y^\ell_m$ correspond to the “kets” $|\ell, m\rangle$ introduced in Section 1.1 of Chapter 6, equation (1.7). More precisely, the formulas (3.3), (3.4), and (3.5) show that one defines an isomorphism of $(\tilde{H}^{(\ell)}, \sigma^\ell)$ onto $(V^\ell, D^\ell)$ by mapping the basis $Y^\ell_m$ to the basis $|\ell, m\rangle$.

**Remark.** We know that $J^2$ commutes with the operators $J_k$, $k = 1, 2, 3$. Because the operators $J^2$ and $J_3$ commute, we can diagonalize them simultaneously. This is what we have done by our choice of the basis $(Y^\ell_m)$.

We would like to show that for the scalar product $\langle \quad | \quad \rangle$, this basis is orthonormal. We know already that it is orthogonal. We show next that for fixed $\ell$, all the basis vectors $Y^\ell_m$ of $\tilde{H}^{(\ell)}$ have the same norm, using the equalities (3.4) and (3.5) and the fact that $J_+$ and $J_-$ are adjoints of one another. For $-\ell + 1 \leq m \leq \ell$,

$$\langle J_+ Y^\ell_{m-1} | Y^\ell_m \rangle = \sqrt{(\ell + m)(\ell - m + 1)} \langle Y^\ell_{m-1} | Y^\ell_m \rangle,$$

while

$$\langle Y^\ell_{m-1} | J_- Y^\ell_m \rangle = \sqrt{(\ell + m)(\ell - m + 1)} \langle Y^\ell_{m-1} | Y^\ell_{m-1} \rangle.$$ 

Because these two quantities are equal, we conclude, by induction on $m$, that all the vectors $Y^\ell_m$ have the same norm. It suffices then to calculate $\langle Y^\ell_m | Y^\ell_m \rangle$. The polynomial $Q^\ell_\ell$ is the constant $(-1)^\ell (2\ell)!$, and consequently,

$$Y^\ell_\ell(\theta, \phi) = (-1)^\ell \gamma^\ell_\ell (2\ell)! \sin^\ell \theta e^{i\ell\phi}.$$

We then have

$$\langle Y^\ell_\ell | Y^\ell_\ell \rangle = \gamma^\ell_\ell \mathcal{I}_\ell,$$

where

$$\gamma^\ell_\ell = 2\pi (\gamma^\ell_\ell (2\ell)!)^2$$

and

$$\mathcal{I}_\ell = \int_0^\pi \sin^{2\ell+1} \theta \, d\theta.$$
We have $I_0 = 2$ and $\gamma_0 = 1/2$, whence $\langle Y_0^0 | Y_0^0 \rangle = 1$. Integration by parts shows that $I_{\ell+1} = I_\ell - \frac{1}{2\ell+2} I_{\ell+1}$, that is, $(2\ell + 3)I_{\ell+1} = (2\ell + 2)I_\ell$. Because $(2\ell + 2)\gamma_{\ell+1} = (2\ell + 3)\gamma_\ell$, we can deduce that
\[ \langle Y_\ell^\ell | Y_\ell^\ell \rangle = 1, \]
for every $\ell \in \mathbb{N}$. By Theorem 3.2, we can thus state the following theorem.

**Theorem 3.4.** The spherical harmonics $Y_{\ell}^m$, $\ell \in \mathbb{N}$, $-\ell \leq m \leq \ell$, form a Hilbert basis of $L^2(S^2)$ equipped with the unnormalized scalar product.

In other words, each function belonging to $L^2(S^2)$ has a series expansion in spherical harmonics, convergent in the sense of the norm of $L^2(S^2)$,
\[ f = \sum_{\ell=0}^{\infty} \sum_{-\ell \leq m \leq \ell} f_m^\ell Y_m^\ell = f_0^0 Y_0^0 + f_1^1 Y_1^1 + f_1^0 Y_1^0 + f_{-1}^1 Y_{-1}^1 + \cdots, \]
where the coefficients of the expansion are given by the unnormalized scalar products of functions on the sphere,
\[ f_m^\ell = \langle Y_m^\ell | f \rangle. \]

**Remark.** The Legendre polynomials are defined, for $\ell \in \mathbb{N}$, by
\[ P_\ell(x) = (-1)^\ell \frac{d^\ell}{dx^\ell}(1 - x^2)^\ell, \]
and the Legendre functions are defined, for $m \in \mathbb{N}$ and for $x \in [-1, 1]$, by
\[ P_{\ell,m}(x) = (-1)^m (1 - x^2)^{\frac{m}{2}} \frac{d^m}{dx^m} P_\ell(x) = (-1)^{\ell+m} \frac{2^\ell \ell!}{2^\ell \ell!} (1 - x^2)^{\frac{m}{2}} \frac{d^{\ell+m}}{dx^{\ell+m}} (1 - x^2)^\ell. \]

In general one expresses the spherical harmonics $Y_m^\ell$ by means of the Legendre functions $P_{\ell,m}$. We see that for $m \geq 0$,
\[ Y_m^\ell(\theta, \phi) = \gamma_{\ell,m} P_{\ell,m}(\cos \theta)e^{im\phi}, \]
where
\[ \gamma_{\ell,m} = \frac{\sqrt{2\ell + 1}}{4\pi} \sqrt{\frac{(\ell - m)!}{(\ell + m)!}}. \]

The functions denoted by $Z_m^\ell(\theta)$ above differ from the Legendre functions $P_{\ell,m}(\cos \theta)$ only by a numerical factor,
\[ Z_m^\ell(\theta) = (-1)^{\ell+m} \frac{2^\ell \ell!}{2^\ell \ell!} P_{\ell,m}(\cos \theta), \]
and the constants $\gamma_m^\ell$ and $\gamma_{\ell,m}$ are related by
\[ \gamma_m^\ell = \frac{(-1)^{\ell+m}}{2^\ell \ell!} \gamma_{\ell,m}. \]
This close link between spherical harmonics and Legendre functions allows us to deduce the properties of Legendre functions from those of spherical harmonics that were proved using the representation theory of groups. This method generalizes to other groups to which there correspond other special functions.

We can obtain the orthonormality property of the basis functions \( Y_{\ell m} \) by expressing them as functions of the matrix coefficients of the unitary representations \( \sigma^{\ell} \) and using the orthogonality relations proved in Theorem 4.4 of Chapter 3 (see Problem 9).

### 3.5 Explicit Formulas

In spectroscopy, the levels \( \ell = 0, 1, 2, 3, 4, 5 \) are denoted by the letters \( s, p, d, f, g, h \). Here are the explicit formulas for the levels \( s, p, \) and \( d \):

<table>
<thead>
<tr>
<th>( \ell )</th>
<th>( Y_0^\ell )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( s )</td>
<td>( Y_0^0 = \sqrt{\frac{1}{4\pi}} )</td>
</tr>
<tr>
<td>( p_0 )</td>
<td>( Y_0^1 = \sqrt{\frac{3}{4\pi}} \cos \theta )</td>
</tr>
<tr>
<td>( p_{\pm} )</td>
<td>( Y_{\pm 1}^{\pm 1} = \mp \sqrt{\frac{3}{8\pi}} \sin \theta \ e^{\pm i\phi} )</td>
</tr>
<tr>
<td>( d_0 )</td>
<td>( Y_0^2 = \sqrt{\frac{5}{16\pi}} (3 \cos^2 \theta - 1) )</td>
</tr>
<tr>
<td>( d_{\pm 1} )</td>
<td>( Y_{\pm 1}^{\pm 1} = \mp \sqrt{\frac{15}{8\pi}} \sin \theta \cos \theta \ e^{\pm i\phi} )</td>
</tr>
<tr>
<td>( d_{\pm 2} )</td>
<td>( Y_{\pm 2}^{\pm 2} = \sqrt{\frac{15}{32\pi}} \sin^2 \theta \ e^{\pm 2i\phi} )</td>
</tr>
</tbody>
</table>

We also calculate for the level \( f \),

\[
Y_0^3 = \sqrt{\frac{7}{16\pi}} \cos \theta (5 \cos^2 \theta - 3),
\]

and so forth.

We also introduce, for \( m > 0 \), real linear combinations of spherical harmonics,

\[
Y_{m,c}^{\ell} = (-1)^m \sqrt{2} \gamma_m \ell Z_m^\ell (\theta) \cos m\phi
\]

and

\[
Y_{m,s}^{\ell} = (-1)^m \sqrt{2} \gamma_m \ell Z_m^\ell (\theta) \sin m\phi.
\]

When one restricts a representation \( D^{\ell} \) to a finite subgroup of SO(3), such as a dihedral group, one obtains a representation, in general not irreducible, of this subgroup. With linear combinations of spherical harmonics \( Y_{m}^{\ell} \), one can construct bases for the spaces of irreducible representations of finite subgroups of SO(3).
The theory of spherical harmonics has vast generalizations in which the groups considered are compact Lie groups more general than \( \text{SO}(3) \). What generalizes the spheres are the homogeneous spaces, which are manifolds that are quotients of Lie groups by closed subgroups.

References

Exercises

Exercise 7.1 Representations of \( \text{SO}(2) \).

Let \((r, \theta)\) be polar coordinates on \( \mathbb{R}^2 \) minus the origin. We recall that the Laplacian in polar coordinates can be written

\[
\Delta = \frac{\partial^2}{\partial r^2} + \frac{1}{r} \frac{\partial}{\partial r} + \frac{1}{r^2} \frac{\partial^2}{\partial \theta^2}.
\]

(a) Show that \( (\sigma(g)f)(x) = f(g^{-1}(x)) \), \( x \in \mathbb{R}^2 \), defines a unitary representation \( \sigma \) of \( \text{SO}(2) \) on \( L^2(\mathbb{R}^2) \).

Denote by \( \mathcal{H}^{(\ell)} \) the vector space of harmonic homogeneous polynomials on \( \mathbb{R}^2 \) of degree \( \ell \), where \( \ell \in \mathbb{N} \).

(b) Find a basis of \( \mathcal{H}^{(\ell)} \).

(c) Show that \( \mathcal{H}^{(\ell)} \) is invariant under \( \sigma \). Is the restriction of \( \sigma \) to \( \mathcal{H}^{(\ell)} \) irreducible for every \( \ell \geq 0 \)? If not, find its decomposition into a direct sum of irreducible representations of \( \text{SO}(2) \).

Exercise 7.2 Orthogonality relations for the Legendre functions.

Deduce from the properties of spherical harmonics the orthogonality relations for the Legendre functions,

\[
\int_{-1}^{1} P_{\ell,m}(x) P_{\ell',m}(x) dx = 0 \quad \text{if} \quad \ell \neq \ell',
\]

and calculate the value of the integral for \( \ell = \ell' \).
Exercise 7.3 Addition theorem for spherical harmonics.

Let $d^\ell_{mn}(\theta), -\ell \leq m \leq \ell, -\ell \leq n \leq \ell, \theta \in [0, \pi]$, be the matrix coefficients of the rotation $\exp(\theta \eta_1)$ in the representation $D^\ell$ in the orthonormal basis $|\ell, m\rangle$. Then

$$d^\ell_{00}(\theta) = P_\ell(\cos \theta),$$

where $P_\ell$ is the $\ell$th Legendre polynomial, and the coefficients $d^\ell_{m0}(\theta)$ are related to the spherical harmonics $Y^\ell_m(\theta, \phi)$ by

$$Y^\ell_m(\theta, \phi) = \sqrt{\frac{2\ell + 1}{4\pi}} (-i)^m d^\ell_{m0}(\theta)e^{im\phi}.$$

These formulas are proved in Problem 9. The factor $(-i)^m$ appears here instead of the factor $i^m$ because $\varphi^\ell_m = (-1)^{\ell-m}|\ell \ell\rangle$ implies $\rho^\ell_{m0} = (-1)^m d^\ell_{m0}$.

(a) Verify these formulas when $\ell = 1$ using the result of Exercise 6.6.

(b) Prove the equation

$$4\pi \frac{2\ell + 1}{2\ell + 1} \sum_{m=-\ell}^\ell Y^\ell_m(\theta, \phi)Y^\ell_m(\theta', \phi) = P_\ell(\cos(\theta - \theta')).$$

This equation, called the addition theorem for spherical harmonics, has important applications in quantum mechanics.

Exercise 7.4 Recurrence relation.

Show that there are constants $\alpha(\ell, m)$ and $\beta(\ell, m)$ such that

$$\cos \theta Y^\ell_m = \alpha(\ell, m)Y^{\ell+1}_m + \beta(\ell, m)Y^{\ell-1}_m.$$
Murray Gell-Mann, born in New York in 1929, Nobel Prize in physics in 1969, member of the Los Alamos National Laboratory and professor at the University of New Mexico, proposed the theory of the eightfold way and quarks in 1961, at about the same time as Ne’eman.

(American Institute of Physics, Emilio Segrè Visual Archives)

Yuval Ne’eman (1925–2006), founder and director of the physics and astronomy department of Tel Aviv University, discovered the SU(3) symmetry of subatomic particles in 1961, at about the same time as Gell-Mann.

(American Institute of Physics, Emilio Segrè Visual Archives)
1. Review of $\mathfrak{sl}(n, \mathbb{C})$, Representations of $\mathfrak{sl}(3, \mathbb{C})$ and SU(3)

1.1 Review of $\mathfrak{sl}(n, \mathbb{C})$

In $\mathfrak{sl}(n, \mathbb{C})$, we denote by $\mathfrak{h}$ the abelian Lie subalgebra of the traceless diagonal matrices. We note that $\mathfrak{h}$ is maximal among the abelian Lie subalgebras of $\mathfrak{sl}(n, \mathbb{C})$. In fact, if a Lie subalgebra of $\mathfrak{sl}(n, \mathbb{C})$ contains $\mathfrak{h}$ and a nondiagonal matrix, it is nonabelian, since no nondiagonal matrix commutes with every traceless diagonal matrix. The Lie subalgebra $\mathfrak{h}$ of $\mathfrak{sl}(n, \mathbb{C})$ is called a Cartan subalgebra of $\mathfrak{sl}(n, \mathbb{C})$.

We denote by $E_{ij}$, $1 \leq i \leq n$, $1 \leq j \leq n$, the matrix having 1 on the intersection of the $i$th line and the $j$th column and having 0 everywhere else. We set $H_i = E_{ii} - E_{i+1,i+1}$. Recall that a basis of $\mathfrak{sl}(n, \mathbb{C})$ is formed by the $E_{ij}$, $1 \leq i \leq n$, $1 \leq j \leq n$, $i \neq j$, and the $H_i$, $i = 1, \ldots, n-1$, where the matrices $H_i$, $i = 1, \ldots, n-1$, are a basis of $\mathfrak{h}$.

We have $E_{ij}E_{kl} = \delta_{jk}E_{il}$, whence the commutation relations of these matrices,

\[
[E_{ij}, E_{kl}] = \delta_{jk}E_{il} - \delta_{il}E_{kj}, \quad (1.1)
\]
\[
[H, E_{ij}] = (\lambda_i - \lambda_j)(H)E_{ij}, \quad (1.2)
\]

where $\lambda_i : H \mapsto \lambda_i(H)$ denotes the linear map of $\mathfrak{h}$ into $\mathbb{C}$ that associates to each traceless diagonal matrix the element on the $i$th line.

1.2 The Case of $\mathfrak{sl}(3, \mathbb{C})$

In the case of $\mathfrak{sl}(3, \mathbb{C})$, the Cartan subalgebra $\mathfrak{h}$ is of dimension 2 and has as a basis

\[
H_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad H_2 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.
\]
We can take as a basis of the vector space of strictly upper triangular matrices,

\[ E_1 = E_{12} = \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \quad E_2 = E_{23} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & 0 \end{pmatrix}, \quad E_3 = E_{13} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \]

and as a basis of the vector space of strictly lower triangular matrices,

\[ F_1 = \,^tE_1 = E_{21}, \quad F_2 = \,^tE_2 = E_{32}, \quad F_3 = \,^tE_3 = E_{31}. \]

We set

\[ H_3 = H_1 + H_2 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & -1 \end{pmatrix}. \]

The commutation relations can be written

\[
\begin{align*}
[H_1, H_2] &= 0, & [E_i, F_i] &= H_i, & i &= 1, 2, 3, \\
[E_1, E_2] &= E_3, & [E_1, E_3] &= 0, & [E_2, E_3] &= 0, \\
[F_1, F_2] &= -F_3, & [F_1, F_3] &= 0, & [F_2, F_3] &= 0,
\end{align*}
\]

and

\[
\begin{align*}
[E_1, F_2] &= 0, & [E_2, F_1] &= 0, \\
[E_1, F_3] &= -F_2, & [E_3, F_1] &= -E_2, \\
\end{align*}
\]

The remaining commutation relations will interest us more particularly in what follows. Some of them say that \( E_1, E_2, \) and \( E_3 \) are common eigenvectors of the endomorphisms \( \text{ad}_H \) and \( \text{ad}_H \) of \( g = \text{sl}(3, \mathbb{C}), \)

\[
\begin{align*}
[H_1, E_1] &= 2E_1, & [H_2, E_1] &= -E_1, \\
[H_1, E_2] &= -E_2, & [H_2, E_2] &= 2E_2, \\
[H_1, E_3] &= E_3, & [H_2, E_3] &= E_3.
\end{align*}
\]

The others say that, similarly, \( F_1, F_2, \) and \( F_3 \) are common eigenvectors of the endomorphisms \( \text{ad}_H \) and \( \text{ad}_H \),

\[
\begin{align*}
[H_1, F_1] &= -2F_1, & [H_2, F_1] &= F_1, \\
[H_1, F_2] &= F_2, & [H_2, F_2] &= -2F_2, \\
\end{align*}
\]

We let \( \alpha_1(H_1) \) (respectively, \( \alpha_1(H_2) \)) denote the eigenvalue of \( \text{ad}_H \) (respectively, \( \text{ad}_H \)) corresponding to the eigenvector \( E_1 \). By the preceding formulas,

\[ \alpha_1(H_1) = 2, \quad \alpha_1(H_2) = -1. \]

In fact, each element of the Cartan subalgebra \( h \) can be written as a linear combination of \( H_1 \) and \( H_2 \), and we thus define a linear form \( \alpha_1 \) on \( h \).
The values of this linear form on the basis vectors \((H_1, H_2)\), are \((2, -1)\). These are also the components of this linear form in the basis dual to the basis \((H_1, H_2)\), by the definition of the notion of dual basis. We introduce similarly the notation \(\alpha_2(H)\) for the eigenvalues of \(H \in \mathfrak{h}\) corresponding to the eigenvector \(E_2\),
\[
\alpha_2(H_1) = -1, \quad \alpha_2(H_2) = 2.
\]

Finally, let \(\alpha_3(H)\) be the eigenvalue of \(H \in \mathfrak{h}\) corresponding to the eigenvector \(E_3\),
\[
\alpha_3(H_1) = 1, \quad \alpha_3(H_2) = 1.
\]

We clearly have
\[
\alpha_3 = \alpha_1 + \alpha_2.
\]

By definition,
\[
[H_i, E_j] = \alpha_j(H_i)E_j, \quad 1 \leq i \leq 3, \quad 1 \leq j \leq 3,
\]
and we also see that
\[
[H_i, F_j] = -\alpha_j(H_i)F_j, \quad 1 \leq i \leq 3, \quad 1 \leq j \leq 3.
\]

The linear forms \(\alpha_1, \alpha_2, \alpha_3, -\alpha_1, -\alpha_2, -\alpha_3\) on \(\mathfrak{h}\) play an important role in representation theory. They are called the roots of \(\mathfrak{sl}(3, \mathbb{C})\).

Above we have introduced the linear form on \(\mathfrak{h}\), denoted by \(\lambda_i\), that associates to each matrix in \(\mathfrak{h}\) the element on the \(i\)th line. We see immediately, directly or from (1.2), that
\[
\alpha_1 = \lambda_1 - \lambda_2, \quad \alpha_2 = \lambda_2 - \lambda_3, \quad \alpha_3 = \lambda_1 - \lambda_3.
\]

### 1.3 The Bases \((I_3, Y)\) and \((I_3, T_8)\) of \(\mathfrak{h}\)

In the Cartan subalgebra \(\mathfrak{h}\) of \(\mathfrak{sl}(3, \mathbb{C})\) we introduce a new basis \((I_3, Y)\) defined by
\[
I_3 = \frac{1}{2}H_1, \quad Y = \frac{1}{3}(H_1 + 2H_2) = \frac{1}{3}\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -2
\end{pmatrix}.
\]

We introduce also
\[
T_8 = \frac{\sqrt{3}}{2}Y = \frac{1}{2\sqrt{3}}\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -2
\end{pmatrix},
\]
and we consider the basis \((I_3, T_8)\) of \(\mathfrak{h} \subset \mathfrak{sl}(3, \mathbb{C})\) as well.

**Remark.** In many physics books, \(I_3\) is denoted by \(T_3\). The quantity \(Q = \frac{1}{2}Y + I_3\) is introduced as well. The eigenvalues of the operators \(I_3, Y,\) and \(Q\) of the symmetry algebra in a representation correspond to the third component of the isospin, to the hypercharge, and to the electric charge, respectively.
1.4 Representations of sl(3, C) and of SU(3)

There is a bijection between the irreducible representations of sl(3, C) and those of su(3), by complexification and, conversely, by restriction. Furthermore, the irreducible representations of the Lie algebra su(3) are in bijective correspondence with those of the Lie group SU(3), since this group is connected and simply connected.

2 The Adjoint Representation and Roots

In what follows we are interested in the representations of the Lie group SU(3). By the preceding remarks, it suffices to study the representations of the Lie algebra sl(3, C), which is of complex dimension 8. We make use of the notation of Section 1.1. The commutation relations of sl(3, C) imply that if

\[ H = \begin{pmatrix} \lambda_1(H) & 0 & 0 \\ 0 & \lambda_2(H) & 0 \\ 0 & 0 & \lambda_3(H) \end{pmatrix}, \]

then \[ [H, E_{ij}] = (\lambda_i(H) - \lambda_j(H))E_{ij}. \]

The roots of sl(3, C) are thus given by the following table:

<table>
<thead>
<tr>
<th>root</th>
<th>relations</th>
<th>basis (I_3,Y)</th>
<th>basis(I_3,T_8)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\alpha_1)</td>
<td>([I_3, E_1] = E_1) ([Y, E_1] = 0)</td>
<td>(1,0)</td>
<td>(1,0)</td>
</tr>
<tr>
<td>(\alpha_2)</td>
<td>([I_3, E_2] = -\frac{1}{2}E_2) ([Y, E_2] = E_2)</td>
<td>((-\frac{1}{2}, 1))</td>
<td>((-\frac{1}{2}, -\frac{\sqrt{3}}{2}))</td>
</tr>
<tr>
<td>(\alpha_3)</td>
<td>([I_3, E_3] = \frac{1}{2}E_3) ([Y, E_3] = E_3)</td>
<td>((\frac{1}{2}, 1))</td>
<td>((\frac{1}{2}, \frac{\sqrt{3}}{2}))</td>
</tr>
<tr>
<td>(\alpha'_1)</td>
<td>([I_3, F_1] = -F_1) ([Y, F_1] = 0)</td>
<td>((-1,0))</td>
<td>((-1,0))</td>
</tr>
<tr>
<td>(\alpha'_2)</td>
<td>([I_3, F_2] = \frac{1}{2}F_2) ([Y, F_2] = -F_2)</td>
<td>((\frac{1}{2}, -1))</td>
<td>((\frac{1}{2}, -\frac{\sqrt{3}}{2}))</td>
</tr>
<tr>
<td>(\alpha'_3)</td>
<td>([I_3, F_3] = -\frac{1}{2}F_3) ([Y, F_3] = -F_3)</td>
<td>((-\frac{1}{2}, -1))</td>
<td>((-\frac{1}{2}, -\frac{\sqrt{3}}{2}))</td>
</tr>
</tbody>
</table>

The following equalities are obvious:

\[ \alpha_3 = \alpha_1 + \alpha_2, \quad \alpha'_1 = -\alpha_1, \quad \alpha'_2 = -\alpha_2, \quad \alpha'_3 = -\alpha_3. \]

The first can also be seen as a consequence of the Jacobi identity, because

\[ [H_i, E_3] = [H_i, [E_1, E_2]] = [[H_i, E_1], E_2] + [E_1, [H_i, E_2]] = \alpha_1(H_i)[E_1, E_2] + \alpha_2(H_i)[E_1, E_2] = (\alpha_1 + \alpha_2)(H_i)E_3. \]

We recall also that \(\alpha_1 = \lambda_1 - \lambda_2\) and \(\alpha_2 = \lambda_2 - \lambda_3\).

Now we draw the roots of sl(3, C) in the plane relative to the axes \(I_3\) and \(T_8\) (Figure 1). We see that these six roots form a regular hexagon, which would not have been the case had we used the basis \((I_3, Y)\). Technically, 0 is not called a root, but for every \(H \in \mathfrak{h}\), 0 is a double eigenvalue of the endomorphism \(\text{ad}_H\). This is why we draw the point 0 as a double point (a point surrounded by a little circle). The adjoint representation is of dimension 8, and we shall denote it in the rest of this chapter by \(8\). In the following sections, we shall talk more generally of weights of representations of the algebra sl(3, C) and we shall see that the roots are the weights of the adjoint representation.
3 The Fundamental Representation and Its Dual

3.1 The Fundamental Representation

Now we consider the fundamental representation. We have

\[ H_1 e_1 = e_1, \quad H_2 e_1 = 0, \]
\[ H_1 e_2 = -e_2, \quad H_2 e_2 = e_2, \]
\[ H_1 e_3 = 0, \quad H_2 e_3 = -e_3. \]

By definition, the weights of this representation are the linear forms \( \lambda_1, \lambda_2, \) and \( \lambda_3 \) on \( \mathfrak{h} \) satisfying, for \( H \in \mathfrak{h} \) and \( i = 1, 2, 3, \)

\[ He_i = \lambda_i(H)e_i. \]

Thus in the basis \((H_1, H_2)\) the components of the three weights are

\[ \lambda_1 = (1, 0), \quad \lambda_2 = (-1, 1), \quad \lambda_3 = (0, -1). \]

Hence we have the following table:

<table>
<thead>
<tr>
<th>weight</th>
<th>relations</th>
<th>basis ((I_3, Y))</th>
<th>basis((I_3, T_8))</th>
<th>quark</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\lambda_1)</td>
<td>(I_3e_1 = \frac{1}{2}e_1) (Ye_1 = \frac{1}{3}e_1)</td>
<td>((\frac{1}{2}, \frac{1}{3}))</td>
<td>((\frac{1}{2}, \frac{1}{2\sqrt{3}}))</td>
<td>(u)</td>
</tr>
<tr>
<td>(\lambda_2)</td>
<td>(I_3e_2 = -\frac{1}{2}e_2) (Ye_2 = \frac{1}{3}e_2)</td>
<td>((-\frac{1}{2}, \frac{1}{3}))</td>
<td>((-\frac{1}{2}, \frac{1}{2\sqrt{3}}))</td>
<td>(d)</td>
</tr>
<tr>
<td>(\lambda_3)</td>
<td>(I_3e_3 = 0) (Ye_3 = -\frac{2}{3}e_3)</td>
<td>((0, -\frac{2}{3}))</td>
<td>((0, \frac{1}{3\sqrt{3}}))</td>
<td>(s)</td>
</tr>
</tbody>
</table>
Thus there are three linearly independent vectors $e_1, e_2, e_3$ that are common eigenvectors of all elements $H$ of $\mathfrak{h}$. We denote them by $u$, $d$, $s$, which designate the quarks,

$u = \text{up}, \ d = \text{down}, \ s = \text{strange}.$

(See more information on the quarks in Sections 6 and 7 below.)

In the basis $(I_3, T_8)$, the weights $\lambda_1 = w_u, \lambda_2 = w_d, \lambda_3 = w_s$ of the fundamental representation form an equilateral triangle. We have

$$\lambda_1 + \lambda_2 + \lambda_3 = 0.$$ 

In Figure 2 we draw the weight diagram of the fundamental representation of $\mathfrak{sl}(3, \mathbb{C})$, which we shall call $\mathbf{3}$ from now on.

![Figure 2. The representation $\mathbf{3}$.](image)

### 3.2 The Dual of the Fundamental Representation

We pass from the fundamental representation to its dual by replacing the matrices $X \in \mathfrak{sl}(3, \mathbb{C})$ by $X' = -{}^t X$, and so $H'_j e_i = -\lambda_i (H_j) e_i$. The equations

$$H'_1 e_1 = -e_1, \quad H'_2 e_1 = 0, \quad H'_1 e_2 = e_2, \quad H'_2 e_2 = -e_2, \quad H'_1 e_3 = 0, \quad H'_2 e_3 = e_3,$$

show that the components of the three weights $\lambda'_1, \lambda'_2, \lambda'_3$ of this representation in the basis $(H_1, H_2)$ are

$$\lambda'_1 = (-1, 0), \quad \lambda'_2 = (1, -1), \quad \lambda'_3 = (0, 1).$$

One obtains thus the following table for the weights of the dual representation of the fundamental representation:
Highest Weight of a Finite-Dimensional Representation

<table>
<thead>
<tr>
<th>weight'</th>
<th>relations</th>
<th>basis ((I_3, Y))</th>
<th>basis ((I_3, T_8))</th>
<th>antiquarks</th>
</tr>
</thead>
<tbody>
<tr>
<td>(\lambda_1')</td>
<td>(I_3e_1 = -\frac{1}{2}e_1) (Ye_1 = -\frac{1}{3}e_1)</td>
<td>((-\frac{1}{2}, -\frac{1}{3}))</td>
<td>((-\frac{1}{2}, -\frac{1}{2\sqrt{3}}))</td>
<td>(\bar{u})</td>
</tr>
<tr>
<td>(\lambda_2')</td>
<td>(I_3e_2 = \frac{1}{2}e_2) (Ye_2 = -\frac{1}{3}e_2)</td>
<td>((\frac{1}{2}, -\frac{1}{3}))</td>
<td>((\frac{1}{2}, -\frac{1}{2\sqrt{3}}))</td>
<td>(\bar{d})</td>
</tr>
<tr>
<td>(\lambda_3')</td>
<td>(I_3e_3 = 0) (Ye_3 = \frac{2}{3}e_3)</td>
<td>((0, \frac{2}{3}))</td>
<td>((0, \frac{1}{\sqrt{3}}))</td>
<td>(\bar{s})</td>
</tr>
</tbody>
</table>

The weight vectors \(\bar{u}, \bar{d},\) and \(\bar{s}\) are called the *antiquarks*.

In Figure 3 we draw the weight diagram of the representation dual to the fundamental representation of \(\mathfrak{sl}(3, \mathbb{C})\), which we shall call \(\bar{3}\) from now on.

![Figure 3. The representation \(\bar{3}\).](image)

4 Highest Weight of a Finite-Dimensional Representation

4.1 Highest Weight

A *weight* of a representation \((E, \rho)\) is a linear form \(\omega\) on \(\mathfrak{h}\) such that there is a nonzero vector \(v \in E\) satisfying \(\rho(H)v = \omega(H)v\) for every \(H \in \mathfrak{h}\).

We shall see that in each of the three representations described above, one of the weights plays a particular role. It will be called the *highest weight* of the representation. An eigenvector corresponding to the highest weight, which is defined up to multiplication by a nonzero scalar, is called the *highest-weight vector*.

**Example 1.** In \(3\), the highest weight is \(\lambda_1 = w_u\), with highest-weight vector \(e_1 = u\). We verify the following properties:

(i) \(H_1e_1 = e_1,\) \(H_2e_1 = 0\) \((e_1\) is an eigenvector for each \(H \in \mathfrak{h}\)),

(ii) \(E_ie_1 = 0,\) \(i = 1, 2, 3\).

Furthermore, we obtain \(e_2\) and \(e_3\) by the action of \(F_1, F_2,\) and \(F_3\) on \(e_1\). More precisely,

\[ F_1e_1 = e_2, \quad F_2e_1 = 0, \quad F_3e_1 = e_3. \]
Example 2. In $\mathfrak{f}$, the highest weight is $\lambda'_3 = w_\pi$, with highest-weight vector $e_3 = \bar{s}$, that is,

$(i) \quad H'_1 e_3 = 0, \quad H'_2 e_3 = e_3 \quad (e_3$ is an eigenvector of each $H \in \mathfrak{h}$),

$(ii) \quad E'_i e_3 = -F_i e_3 = 0, \quad i = 1, 2, 3.$

As in the preceding example, we obtain scalar multiples of $e_1$ and $e_2$ by the action of $F'_1, F'_2, \text{and } F'_3$ on $e_3$. More precisely,

$F'_1 e_3 = -E_1 e_3 = 0, \quad F'_2 e_3 = -E_2 e_3 = -e_2, \quad F'_3 e_3 = -E_3 e_3 = -e_1.$

Example 3. In $\mathfrak{g}$, the highest weight is $\alpha_3$, with highest-weight vector $E_3$. We have

$(i) \quad [H_1, E_3] = E_3, \quad [H_2, E_3] = E_3 \quad (E_3$ is an eigenvector of each $H \in \mathfrak{h}$),

$(ii) \quad [E_i, E_3] = 0, \quad i = 1, 2, 3.$

Here we obtain scalar multiples of $E_1, E_2, F_1, F_2, F_3, H_1, H_2$ by the action of $F_1, F_2, \text{and } F_3$ on $E_3$. More precisely,

$[F_1, E_3] = E_2, \quad [F_2, E_3] = -E_1, \quad [F_3, E_3] = -H_3,$

$[F_2, [F_1, E_3]] = -H_2, \quad [F_3, [F_1, E_3]] = -F_1,$

$[F_1, [F_2, E_3]] = -H_1, \quad [F_3, [F_2, E_3]] = F_2,$

$[F_3, [F_3, E_3]] = -2F_3.$

In summary, we have seen that for the representations $\rho$ studied so far, there is a highest weight $w_{\text{max}}$ and a vector $e_{\text{max}}$ called highest-weight vector, defined up to multiplication by a nonzero scalar, satisfying the following properties:

$(i) \quad$ for every $H \in \mathfrak{h}$, the vector $e_{\text{max}}$ is an eigenvector of $\rho(H)$ for the eigenvalue $w_{\text{max}}(H)$,

$(ii) \quad$ for $i = 1, 2, 3, \quad \rho(E_i)(e_{\text{max}}) = 0,$

$(iii) \quad$ the images of the vector $e_{\text{max}}$ by repeated application of the operators $\rho(F_i)$, for $i = 1, 2, 3$, generate the entire space of the representation.

4.2 Weights as Linear Combinations of the $\lambda_i$

We have set

$$H = \begin{pmatrix} \lambda_1(H) & 0 & 0 \\ 0 & \lambda_2(H) & 0 \\ 0 & 0 & \lambda_3(H) \end{pmatrix},$$

and thus defined linear forms $\lambda_1, \lambda_2, \text{and } \lambda_3$ on $\mathfrak{h}$. We shall see that each weight of the representations above can be written

$$w = m_1\lambda_1 + m_2\lambda_2 + m_3\lambda_3$$

(which means that $w(H) = m_1\lambda_1(H) + m_2\lambda_2(H) + m_3\lambda_3(H)$, for every $H \in \mathfrak{h}$),

where the $m_i$ are integers. We can denote a weight by a triple $(m_1, m_2, m_3)$. 
Such a triple is not unique. In fact, $\lambda_1 + \lambda_2 + \lambda_3 = 0$, and consequently we can always reduce to the case in which one of the $m_i$ is zero. For example, we can write

$$w = (m_1 - m_3)\lambda_1 + (m_2 - m_3)\lambda_2 + m_3(\lambda_1 + \lambda_2 + \lambda_3) = m_1'\lambda_1 + m_2'\lambda_2.$$  

We can also reduce to the case in which the $m_i$ are all three positive or zero, as we shall show in the following examples.

**Example 1. The representation 3.** In 3, the weights are

$$w_u = \lambda_1, \ w_d = \lambda_2, \ w_s = \lambda_3.$$  

We see that

$$w_u = \lambda_1 = \lambda_1 + 0\lambda_2 + 0\lambda_3 \rightarrow (1, 0, 0),$$

$$w_d = \lambda_2 = 0\lambda_1 + 1\lambda_2 + 0\lambda_3 \rightarrow (0, 1, 0),$$

$$w_s = \lambda_3 = 0\lambda_1 + 0\lambda_2 + 1\lambda_3 \rightarrow (0, 0, 1).$$  

**Example 2. The representation 3.** In 3, the weights are

$$w_u = -\lambda_1, \ w_d = -\lambda_2, \ w_s = -\lambda_3.$$  

We then have

$$w_u = -\lambda_1 = \lambda_1 + \lambda_2 + \lambda_3 \rightarrow (0, 1, 1),$$

$$w_d = -\lambda_2 = \lambda_1 + \lambda_3 \rightarrow (1, 0, 1),$$

$$w_s = -\lambda_3 = \lambda_1 + \lambda_2 \rightarrow (1, 1, 0).$$  

**Example 3. The representation 8.** In the representation 8, the weights are the roots $\alpha_i, -\alpha_i$, $i = 1, 2, 3$. We see that

$$\alpha_1 = \lambda_1 - \lambda_2 \rightarrow (2, 0, 1), \quad \alpha_1' = \lambda_2 - \lambda_1 \rightarrow (0, 2, 1),$$

$$\alpha_2 = \lambda_2 - \lambda_3 \rightarrow (1, 2, 0), \quad \alpha_2' = \lambda_3 - \lambda_2 \rightarrow (1, 0, 2),$$

$$\alpha_3 = \lambda_1 - \lambda_3 \rightarrow (2, 1, 0), \quad \alpha_3' = \lambda_3 - \lambda_1 \rightarrow (0, 1, 2).$$

In these three examples, we see that the highest weight is the one for which the triple $(m_1, m_2, m_3)$ is the largest in lexicographic order.

### 4.3 Finite-Dimensional Representations and Weights

For each finite-dimensional irreducible representation $\rho$ of $\mathfrak{sl}(3, \mathbb{C})$, there are a highest weight $w$ and a highest-weight vector $v$, defined up to multiplication by a nonzero scalar, satisfying, for every $H \in \mathfrak{h}$,

$$\rho(H)v = w(H)v, \quad \rho(E_i)v = 0, \quad i = 1, 2, 3.$$  

Furthermore, the action of compositions of powers of $\rho(F_i)$, $i = 1, 2, 3$, on $v$ generates the entire space of the irreducible representation of $\mathfrak{sl}(3, \mathbb{C})$.  

These facts are a special case of general theorems on the representations of semisimple Lie algebras, for which see the references at the end of this chapter. From the calculation
\[ \rho(H)\rho(F_i)v = \rho(F_i)\rho(H)v + \rho([H,F_i])v = w(H)\rho(F_i)v - \alpha_i(H)\rho(F_i)v, \]
we obtain
\[ \rho(H)\rho(F_i)v = (w - \alpha_i(H))\rho(F_i)v, \] (4.1)
and it follows that each vector \( \rho(F_1)^{k_1}\rho(F_2)^{k_2}\rho(F_3)^{k_3}v \), for nonnegative integers \( k_i, i = 1, 2, 3 \), is a weight vector corresponding to the weight \( w - k_1\alpha_1 - k_2\alpha_2 - k_3\alpha_3 \). The weights thus obtained are part of the translate of the root diagram that contains the point \( w \). The following is a useful rule:

Rule. In the root diagram of \( \mathfrak{sl}(3, \mathbb{C}) \), the weights of an irreducible representation of \( \mathfrak{sl}(3, \mathbb{C}) \) lie on concentric hexagons that may degenerate into triangles. The multiplicity of each weight is 1 on the edge, it increases by 1 on each concentric hexagon approaching the center, and it is constant on the triangles.

For a proof of this rule, see Fulton–Harris (1991).

### 4.4 Another Example: The Representation 6

We consider the representation of highest weight \( w = 2\lambda_1 \). The other weights will be constructed by adding the negative integer multiples of \( \lambda_1 - \lambda_2 \), \( \lambda_2 - \lambda_3 \), and \( \lambda_1 - \lambda_3 \) such that the weights obtained are not higher than the highest weight. Let \( v \) be a highest-weight vector. By definition,
\[ H_1v = 2v, \quad H_2v = 0, \quad E_1v = E_2v = E_3v = 0. \]
Knowing that \( Hv = w(H)v \), we obtain, using equation (4.1),
\[ H(F_i)v = (w - \alpha_i(H))(F_i)v, \]
whence
\[ H(F_1)v = (w - (\lambda_1 - \lambda_2))(H)(F_1)v \]
\[ = (\lambda_1 + \lambda_2)(H)(F_1)v = -\lambda_3(H)(F_1)v, \]
\[ H(F_3)v = (w - (\lambda_1 - \lambda_3))(H)(F_3)v \]
\[ = (\lambda_1 + \lambda_3)(H)(F_3)v = -\lambda_2(H)(F_3)v. \]
By repeated action of \( F_1, F_2, F_3 \), we obtain Figure 4. This representation is of dimension 6, and we shall denote it by 6.
4.5 One More Example: The Representation 10

We consider the representation of highest weight \( w = 3\lambda_1 \). Below is the list of weights of this representation. Because of the applications to particle physics, which we shall discuss briefly in Section 6, we have given the names of the elementary particles associated to each weight, as well as the value of the component of each weight on the element \( Q = \frac{1}{2}Y + I_3 \) that corresponds to the charge of each particle:

<table>
<thead>
<tr>
<th>weight ( w )</th>
<th>( w(I_3) )</th>
<th>( w(Y) )</th>
<th>( w(T_8) )</th>
<th>( w(Q) )</th>
<th>particle</th>
</tr>
</thead>
<tbody>
<tr>
<td>( 3 \lambda_1 )</td>
<td>( \frac{3}{2} )</td>
<td>1</td>
<td>( \frac{\sqrt{3}}{2} )</td>
<td>2</td>
<td>( \Delta^{++} )</td>
</tr>
<tr>
<td>( 2\lambda_1 + \lambda_2 )</td>
<td>( \frac{1}{2} )</td>
<td>1</td>
<td>( \frac{\sqrt{3}}{2} )</td>
<td>1</td>
<td>( \Delta^{+} )</td>
</tr>
<tr>
<td>( \lambda_2 - \lambda_3 = \lambda_1 + 2\lambda_2 )</td>
<td>( -\frac{1}{2} )</td>
<td>1</td>
<td>( \frac{\sqrt{3}}{2} )</td>
<td>0</td>
<td>( \Delta^{0} )</td>
</tr>
<tr>
<td>( 3\lambda_2 )</td>
<td>( -\frac{3}{2} )</td>
<td>1</td>
<td>( \frac{\sqrt{3}}{2} )</td>
<td>-1</td>
<td>( \Delta^{-} )</td>
</tr>
<tr>
<td>( \lambda_2 - \lambda_1 = 2\lambda_2 + \lambda_3 )</td>
<td>-1</td>
<td>0</td>
<td>0</td>
<td>-1</td>
<td>( \Sigma^{*-} )</td>
</tr>
<tr>
<td>( \lambda_3 - \lambda_1 = \lambda_2 + 2\lambda_3 )</td>

<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>
<td>( \Sigma^{*+} )</td>
</tr>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>( \Sigma^{*0} )</td>
<td></td>
</tr>
</tbody>
</table>
In Figure 5 we draw the weight diagram of this representation, which is of dimension 10, and which we denote by the symbol $10$. To each weight corresponds a unique weight vector up to scalar multiplication. This representation is irreducible, since one can show by examining the weight diagram that it is not the direct sum of representations of smaller dimension. In fact, we can give a complete list of these irreducible representations of small dimension:

- the trivial representation, denoted by $1$,
- the fundamental representation $3$,
- the dual $\overline{3}$ of the fundamental representation $3$,
- the representation $6$,
- the dual $\overline{6}$ of the representation $6$,
- the adjoint representation $8$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure5}
\caption{The representation $10$.}
\end{figure}

5 Tensor Products of Representations

Let $(E_1, \rho_1)$ and $(E_2, \rho_2)$ be representations of the same group $G$. We recall that by definition, $\rho_1 \otimes \rho_2$ is the representation of $G$ on $E_1 \otimes E_2$ defined by

$$(\rho_1 \otimes \rho_2)(g)(v_1 \otimes v_2) = \rho_1(g)v_1 \otimes \rho_2(g)v_2,$$
for $g \in G$ and $v_1 \in E_1$, $v_2 \in E_2$. Then the differential of this representation satisfies equation (7.9) of Chapter 4,

$$D(\rho_1 \otimes \rho_2)(X)(v_1 \otimes v_2) = (D\rho_1)(X)v_1 \otimes v_2 + v_1 \otimes (D\rho_2)(X)v_2,$$

for every $X \in \mathfrak{g}$. Abusing language, we write

$$D(\rho_1 \otimes \rho_2) = D\rho_1 \otimes D\rho_2.$$

The following result is almost obvious given the formula above, but it is very important, and is in fact valid in general.

**Proposition 5.1.** If $v_1$ is a weight vector of a representation $R_1$ of $\mathfrak{sl}(3, \mathbb{C})$ for a weight $w_1$, and if $v_2$ is a weight vector of a representation $R_2$ of $\mathfrak{sl}(3, \mathbb{C})$ for a weight $w_2$, then $v_1 \otimes v_2$ is a weight vector of the representation $R_1 \otimes R_2$ for the weight $w_1 + w_2$.

**Example 1:** $3 \otimes \overline{3}$. We shall treat the example of the representation $3 \otimes \overline{3}$ graphically (see Figure 6). We see that

$$3 \otimes \overline{3} = 8 \oplus 1.$$

The weight 0 is of multiplicity 3, and the other weights are of multiplicity 1.

**Example 2:** $3 \otimes 3 \otimes 3$. In this tensor product, there are three weights of multiplicity 1, six weights of multiplicity 3, and the weight 0 is of multiplicity 6 (see Figure 7). We obtain

$$3 \otimes 3 \otimes 3 = 10 \oplus 8 \oplus 8 \oplus 1.$$
The table below gives the components of the weights with the corresponding weight vectors:

<table>

Figure 7. $3 \otimes 3 \otimes 3 = 10 \oplus 8 \oplus 8 \oplus 1$. 
6 The Eightfold Way

Up until 1955, scientists had observed seven baryons, and an eighth was observed in 1958, the \( \Xi^0 \). On the other hand, there were seven known mesons. This set of observations led Murray Gell-Mann and Yuval Ne’eman, independently, during the winter of 1960–1961, to propose the symmetry group SU(3) for the classification of the elementary particles. The eight baryons were grouped in the octet of the adjoint representation, and the seven known mesons formed part of such an octet. The publication of Ne’eman’s results took place in 1961, while the internal report of the California Institute of Technology by Gell-Mann was not published as an article in Physical Review until 1962. The particle \( \eta \) completing the octet of mesons and whose existence was predicted by this theory was discovered in 1962.

The basic idea is that each elementary particle “is” a weight vector of the representation. To each weight vector corresponds a weight that is the collection of the eigenvalues of the operators associated to the chosen basis vectors in the Cartan subalgebra. Thus each weight is defined by two numbers, the eigenvalues of \( H_1 \) and \( H_2 \), or of \( I_3 \) and \( Y \), or of \( I_3 \) and \( T_8 \), according to the basis chosen. These two numbers are the quantum numbers, which characterize the particle when the weight is simple:

- the quantum number corresponding to \( I_3 \) is the third component of the isospin;
- the quantum number corresponding to \( Y \) is the hypercharge.

Then the charge is \( Q = \frac{1}{2} Y + I_3 \), and furthermore, \( Y = B + S \), where \( B \) is the baryon number and \( S \) is the strangeness, which is zero for the proton and the neutron, and for the three \( \pi \) mesons.

The baryon and meson octets were obtained as the representation 8 of SU(3), whence the name of eightfold way given to the theory, echoing the “noble eightfold path” of Buddhism.

Other extremely short-lived elementary particles called resonances were observed in 1961, the four \( \Delta \) and the three \( \Sigma^* \). These corresponded to seven of the ten points of the weight diagram of the representation 10 of SU(3). The theory predicted the existence of two particles of hypercharge \(-1\), the \( \Xi^* \), which were discovered in 1962, as well as the particle corresponding to the tenth point, which was called \( \Omega^- \), and was discovered later, in 1964. This discovery was a great success for the SU(3) theory.

We reproduce below tables of baryons and of mesons, the corresponding diagrams (Figures 8a and 9a), and the diagram of baryon resonances (Figure 10a), all three adapted from Sternberg (1994), as well as the same diagrams (Figures 8b, 9b, and 10b) adapted from Blaizot–Tolédano (1997). We recognize immediately the weight diagram of the representation 8 for the baryons and the mesons, and that of the representation 10 for the baryon resonances. In these tables, \( J \) denotes the spin and \( I \) the isospin of the particle.

For the meson \(\eta\), \(S = 0\), \(I = 0\), \(I_3 = 0\), \(Q = 0\), \(J = 0\). Its mass is \(548 \text{ MeV}/c^2\).
6.3 Baryon Resonances

The observed and predicted baryon resonances belong to the weight diagram of the representation 10 as shown in Figures 10a, b.

The baryon resonances have a very short half-life, of order $10^{-23}$ s for $\Delta^{++}$, $\Delta^+$, $\Delta^0$, and $\Delta^-$.
Quarks and Antiquarks

However, the representations $\mathbf{3}$ and $\mathbf{\bar{3}}$ did not correspond to any observed particle. The quark model allows us to consider the hadrons (baryons and mesons) as “states composed of quarks and antiquarks.” Mathematically, this means the following:

- The quarks are the particles corresponding to the representation $\mathbf{3}$ of SU(3): the three quarks, $u$ (up), $d$ (down), and $s$ (strange), are the weight vectors of this representation:

  \[
  \begin{array}{c|cccc}
  \mathbf{3} & w & w(I_3) & w(Y) & w(T_8) & w(Q) \\
  \hline
  u & w_u = \lambda_1 & \frac{1}{2} & \frac{1}{3} & \frac{1}{2\sqrt{3}} & \frac{2}{3} \\
  d & w_d = \lambda_2 & -\frac{1}{2} & \frac{1}{3} & \frac{1}{2\sqrt{3}} & -\frac{1}{3} \\
  s & w_s = \lambda_3 = -\lambda_1 - \lambda_2 & 0 & -\frac{2}{3} & -\frac{1}{2\sqrt{3}} & -\frac{1}{3} \\
  \end{array}
  \]

- The antiquarks are the particles corresponding to the representation $\mathbf{\bar{3}}$ of SU(3): the three antiquarks, $\bar{u}, \bar{d},$ and $\bar{s}$, are the weight vectors of this representation:

  \[
  \begin{array}{c|cccc}
  \mathbf{\bar{3}} & w & w(I_3) & w(Y) & w(T_8) & w(Q) \\
  \hline
  \bar{u} & w_{\bar{u}} = \lambda_2 + \lambda_3 = -\lambda_1 & -\frac{1}{2} & -\frac{1}{3} & -\frac{1}{2\sqrt{3}} & -\frac{2}{3} \\
  \bar{d} & w_{\bar{d}} = \lambda_1 + \lambda_3 = -\lambda_2 & \frac{1}{2} & -\frac{1}{3} & -\frac{1}{2\sqrt{3}} & \frac{1}{3} \\
  \bar{s} & w_{\bar{s}} = \lambda_1 + \lambda_2 = -\lambda_3 & 0 & \frac{2}{3} & \frac{1}{2\sqrt{3}} & \frac{1}{3} \\
  \end{array}
  \]

- One obtains the meson octet in the decomposition of the tensor product $\mathbf{3} \otimes \mathbf{\bar{3}}$, more precisely, $\mathbf{3} \otimes \mathbf{\bar{3}} = \mathbf{8} \oplus \mathbf{1}$, whence “a meson is composed of a quark–antiquark pair.”

- We obtain the baryon octet and decuplet in the decomposition of the tensor product $\mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{10} \oplus \mathbf{8} \oplus \mathbf{8} \oplus \mathbf{1}$, whence “a baryon is composed of three quarks.”

These decompositions were proved graphically in Section 5 above. To avoid difficulties due to fractional charges and an incompatibility with the Pauli exclusion principle, an additional SU(3) symmetry was in fact introduced later, corresponding to a new quantum number, the color, and leading to the theory of quantum chromodynamics.
References

For the proof of the simple connectedness of SU(3), see for example Rossmann (2002) or Hall (2003).

Exercises

Exercise 8.1 Orthonormal basis of $\mathfrak{h}$

(a) Show that the Killing form of $\mathfrak{sl}(3, \mathbb{C})$ is $K(X,Y) = 6 \text{Tr}XY$.
(b) Equip the Cartan subalgebra $\mathfrak{h}$ with the restriction of the Killing form of $\mathfrak{sl}(3, \mathbb{C})$. Show that $(I_3, Y)$ and $(I_3, T_8)$ are orthogonal bases of $\mathfrak{h}$. Find an orthonormal basis of $\mathfrak{h}$.

Exercise 8.2 The representation $3 \otimes 3$.

Decompose the representation $3 \otimes 3$ of SU(3) into a direct sum of irreducible representations with the help of the weight diagram.

Exercise 8.3 The representation $10$.

Prove that the representation $10$ of SU(3) is irreducible.

Exercise 8.4 On the representation $3 \otimes \overline{3}$.

Prove that the adjoint representation of $\mathfrak{sl}(3, \mathbb{C})$ is equivalent to the restriction of $3 \otimes \overline{3}$ to the smallest invariant subspace containing the vector $u \otimes \overline{u}$. 
Exercise 8.5 Restrictions to \( \mathfrak{sl}(2, \mathbb{C}) \).

The subalgebra \( \mathfrak{g} \) of \( \mathfrak{sl}(3, \mathbb{C}) \) generated by \( E_1, F_1, H_1 \) is isomorphic to \( \mathfrak{sl}(2, \mathbb{C}) \). Decompose the restriction to \( \mathfrak{g} \) of the adjoint representation of \( \mathfrak{sl}(3, \mathbb{C}) \) into a direct sum of irreducible representations of \( \mathfrak{g} \). Same question for the representations 6 and 10.

Exercise 8.6 Representations of dimension 15.

(a) Show that there are four inequivalent irreducible representations of dimension 15 of \( \mathfrak{sl}(3, \mathbb{C}) \), denoted by \( \mathbf{15}, \mathbf{15}', \mathbf{15}'' \), and draw their weight diagrams in the basis \( (I_3, T_8) \).

(b) Show that \( \mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} \otimes \mathbf{3} = \mathbf{3} \oplus 2 \mathbf{6} \oplus \mathbf{3} \mathbf{15} \oplus \mathbf{15}' \).
Eugene Wigner was born in Budapest in 1902 and died in Princeton, NJ, in 1995. He introduced the theory of groups into quantum mechanics as early as 1927 and received the Nobel Prize for physics in 1963 for his discovery of the fundamental symmetry principles in the theory of elementary particles.

1 Restriction of a Representation to a Finite Group

Let Rot\((a, \theta)\) be the rotation of the space \(\mathbb{R}^3\) through the angle \(\theta\) leaving invariant the unit vector \(a\). Consider the rotations, for \(p = 0, 1, 2\),

\[
g_p = \text{Rot}\left(e_3, \frac{2p\pi}{3}\right) \quad \text{and} \quad h_p = \text{Rot}(g_pe_1, \pi),
\]

where \((e_1, e_2, e_3)\) is the canonical basis of \(\mathbb{R}^3\). Set

\[
\Gamma = \{g_0, g_1, g_2, h_0, h_1, h_2\}.
\]

1. Prove the equalities

\[
g_1h_0 = h_0g_2, \quad g_2h_0 = h_0g_1, \quad h_1 = h_0g_1, \quad h_2 = h_0g_2.
\]

Show that \(\Gamma\) is a subgroup of the group of rotations \(\text{SO}(3)\) isomorphic to the symmetric group on three elements, \(\mathfrak{S}_3\).

2. Find the character table of the group \(\Gamma\).

For \(j \in \mathbb{N}\), we denote by \(\mathcal{D}^j\) the representation of \(\text{SO}(3)\) obtained by passing to the quotient in the representation \(\mathcal{D}^j\) of \(\text{SU}(2)\).

3. Show that the value of the character \(\chi_j\) of \(\mathcal{D}^j\) on rotation through an angle \(\theta\), \(\theta \in (0, 2\pi]\), is

\[
\chi_j(\theta) = \frac{\sin(2j + 1)\theta}{\sin \frac{\theta}{2}}.
\]

What is \(\chi_j(0)\)?

4. Find, for each \(j \in \mathbb{N}\), the decomposition of the restriction to \(\Gamma\) of the representation \(\mathcal{D}^j\) into a direct sum of irreducible representations of \(\Gamma\). [Hint: Consider the cases \(j = 3k, j = 3k + 1, j = 3k + 2\), where \(k \in \mathbb{N}\).]
Solutions

1. It is clear that $g_0$ is the identity and that

$$g_2 = (g_1)^2, \quad (gp)^3 = g_0, \quad (hp)^2 = g_0, \quad p = 0, 1, 2.$$ 

We have $h_0 = \exp \pi \eta_1 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}$, $g_1 = \exp \frac{2\pi}{3} \eta_3 = \begin{pmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} & 0 \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} & 0 \\ 0 & 0 & 1 \end{pmatrix}$, $g_2 = \exp \frac{4\pi}{3} \eta_3 = \begin{pmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} & 0 \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} & 0 \\ 0 & 0 & 1 \end{pmatrix}$. By calculating the products of the matrices, we see that $g_1 h_0 = h_0 g_2 = \begin{pmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} & 0 \\ \frac{\sqrt{3}}{2} & -\frac{1}{2} & 0 \\ 0 & 0 & 1 \end{pmatrix}$. We deduce that $g_2 h_0 g_2 = g_2 g_1 h_0 = g_0 h_0 = h_0$, whence $g_2 h_0 = h_0 g_1$.

The rotation $h_1$ leaves $g_1 e_1$ invariant. The same is true of $h_0 g_1$ because $h_0 g_1 (g_1 e_1) = h_0 (g_2 e_1) = g_1 (h_0 e_1) = g_1 e_1$. On the other hand, $h_1$ and $h_0 g_1$ both square to the identity; the rotations $h_1$ and $h_0 g_1$ are thus the same rotation around $g_1 e_1$ and through an angle $\pi$. Similarly, the rotation $h_0 g_2$ leaves $g_2 e_1$ invariant, and squares to the identity; thus it is equal to $h_2$. The set $\Gamma$ is thus

$$\Gamma = \{ g_0, g_1, g_2, h_0, h_0 g_1, h_0 g_2 \}.$$ 

The symmetric group on three elements can be written

$$\mathfrak{S}_3 = \{ e, c, c^2, t, tc, tc^2 \}.$$ 

It is generated by $c$ and $t$ with the relations $c^3 = e$, $t^2 = e$, $ct = tc^2$. We define a bijection $\alpha$ of $\Gamma$ onto $\mathfrak{S}_3$ by setting $\alpha(g_p) = e^p$ and $\alpha(h_p) = tc^p$. The equations shown above imply that $\Gamma$ is a group, and that $\alpha$ is an isomorphism of groups.

2. We denote by $\mathbf{1}$ the trivial one-dimensional representation, by $\epsilon$ the signature representation, and by $\rho_0$ the irreducible representation of dimension 2 of $\mathfrak{S}_3$. The character table of $\Gamma$ is then as follows:

<table>
<thead>
<tr>
<th>$\Gamma$</th>
<th>$g_0$</th>
<th>$g_1$</th>
<th>$h_0$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\chi_\mathbf{1}$</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>$\chi_\epsilon$</td>
<td>1</td>
<td>1</td>
<td>-1</td>
</tr>
<tr>
<td>$\chi_{\rho_0}$</td>
<td>2</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

3. The conjugacy classes of $\text{SO}(3)$ are parametrized by $\theta \in [0, \pi]$. By definition, $\mathcal{D}^j(\text{Rot}(e_3, \theta)) = \mathcal{D}^j(A)$, where $A \in \text{SU}(2)$ is such that $\varphi(A) = \text{Rot}(e_3, \theta)$, where $\varphi$ is the covering morphism of $\text{SU}(2)$ onto $\text{SO}(3)$. Because $\varphi(\pm \exp(\theta \xi_3)) = \exp(\theta \eta_3)$, we have

$$\mathcal{D}^j(\text{Rot}(e_3, \theta)) = \mathcal{D}^j \begin{pmatrix} e^{i\frac{\theta}{2}} & 0 \\ 0 & e^{-i\frac{\theta}{2}} \end{pmatrix}.$$
Thus $\chi_j(\theta) = \chi_j(\theta/2)$, where $\chi_j(t)$ is the value of the character of $D_j$ on the matrix $\begin{pmatrix} e^{it} & 0 \\ 0 & e^{-it} \end{pmatrix}$, that is, $\sin(2j + 1)t / \sin t$. Consequently,

$$\chi_j(\theta) = \frac{\sin(2j + 1)\theta}{2}, \quad 0 \leq \theta \leq \pi.$$  

4. We thus have the following characters:

<table>
<thead>
<tr>
<th>$\Gamma$</th>
<th>(1)</th>
<th>(2)</th>
<th>(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\chi_{3k}$</td>
<td>$6k+1$</td>
<td>1</td>
<td>$(-1)^k$</td>
</tr>
<tr>
<td>$\chi_{3k+1}$</td>
<td>$6k+3$</td>
<td>0</td>
<td>$(-1)^{k+1}$</td>
</tr>
<tr>
<td>$\chi_{3k+2}$</td>
<td>$6k+5$</td>
<td>$-1$</td>
<td>$(-1)^k$</td>
</tr>
</tbody>
</table>

The restriction to the subgroup $\Gamma$ of the representation $D_j$ can be written

$$D_j|_\Gamma = m_1 \mathbf{1} \oplus m_\epsilon \epsilon \oplus m_{\rho_0} \rho_0,$$

where for $\rho = 1, \epsilon, \rho_0$,

$$m_\rho = (\chi_j | \chi_\rho) = \frac{1}{6} \left( (2j + 1)\chi_\rho(g_0) + 2\chi_j(g_1)\chi_\rho(g_1) + 3\chi_j(h_0)\chi_\rho(h_0) \right).$$

Let $j = 3k + r$, where $k$ is an integer and $r = 0, 1, \text{ or } 2$. The calculation of the coefficients $m_1, m_\epsilon, \text{ and } m_{\rho_0}$ gives us the following decomposition. If $j$ is even ($k$ and $r$ have the same parity), then

$$D_j|_\Gamma = (k + 1) \mathbf{1} \oplus k \epsilon \oplus (2k + r) \rho_0.$$

If $j$ is odd ($k$ and $r$ have opposite parity), then

$$D_j|_\Gamma = k \mathbf{1} \oplus (k + 1) \epsilon \oplus (2k + r) \rho_0.$$

In each case we verify that the direct sum is of dimension $2j + 1$.

2 The Group O(2)

Let O(2) be the group of rotations and symmetries of the plane preserving the origin, generated by the matrices

$$r_\theta = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix}, \quad 0 \leq \theta < 2\pi, \quad \text{and} \quad s = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$
1. Find the conjugacy classes of $O(2)$.

2. (a) Show that each irreducible representation of $O(2)$ is of dimension $\leq 2$. 

   [Hint: Consider the restriction of the representation to the subgroup $SO(2)$.

   (b) Find the representations of dimension 1 of $O(2)$.

   (c) Show that the two-dimensional irreducible representations of $O(2)$, up to equivalence, are such that

   $\pi_n(r_\theta) = \begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{pmatrix}$,

   for some integer $n \geq 1$. Find the character $\chi_{\pi_n}$ of $\pi_n$.

3. Let $Ad$ be the adjoint representation of $O(2)$ in its Lie algebra. Show that it is equivalent to one of the representations studied in Question 2.

4. Decompose $\pi_n \otimes \pi_m$, for $n \geq 1$ and $m \geq 1$, into a direct sum of irreducible representations.

5. (a) Show that $r_{2\pi}$ and $s$ generate a subgroup $G$ of $O(2)$ isomorphic to the symmetric group $S_3$ on three elements.

   (b) Find, for every integer $n \geq 1$, the decomposition of the restriction $\sigma_n$ of $\pi_n$ to the subgroup $G$ as a direct sum of irreducible representations. Give a geometric interpretation of the result.

Solutions

1. The equations $s^2 = I$ and $sr_\theta s^{-1} = r_{-\theta}$ imply $r_\theta s = sr_{-\theta}$, whence $r_\theta sr_{-\theta} = sr_{-2\theta}$. Thus the conjugacy class of $s$ is $\{sr_\theta \mid \theta \in [0, 2\pi)\}$. On the other hand, $r_\theta$ and $r_{\theta'}$ are conjugate if and only if $\theta' = \pm \theta$. Thus the other conjugacy classes of $O(2)$ are $\{I\}$, $\{-I\}$, and $\{r_\theta, r_{-\theta}\}$, for $0 < \theta < \pi$.

2. (a) Let $\rho$ be an irreducible representation of $O(2)$ on $\mathbb{C}^d$. Because $SO(2)$ is abelian, the restriction of $\rho$ to $SO(2)$ is a direct sum of representations of dimension 1. Let $x \in \mathbb{C}^d$ be a vector generating one of the lines invariant under the restriction of $\rho$. The vector space generated by $x$ and $\rho(s)x$ is invariant under $O(2)$, since $\rho(r_\theta)\rho(s)x = \rho(s)\rho(r_{-\theta})x$ is collinear with $\rho(s)x$. Because the representation is assumed irreducible, this is the whole space, and thus $d \leq 2$. The representation is of dimension 1 if and only if $x$ and $\rho(s)x$ are collinear.

   (b) Let $\rho : O(2) \to \mathbb{C}$ be a representation of dimension 1 of $O(2)$. One has either $\rho(s) = 1$ or $\rho(s) = -1$. Because $\rho(sr_\theta) = \rho(s)$, we must have $\rho(r_\theta) = 1$, for every $\theta \in [0, 2\pi)$. Thus, either $\rho = \chi_1$ (the trivial representation) or $\rho = \chi'_1$ (the determinant representation).

   (c) Let $\rho : O(2) \to GL(\mathbb{C}^2)$ be a representation of dimension 2 of $O(2)$. There exists $x \in \mathbb{C}^2$ such that $x$ and $\rho(s)x$ are linearly independent (otherwise the representation is of dimension 1). In the basis $(x, \rho(s)x)$ of $\mathbb{C}^2$, the matrix of $\rho(s)$ is $\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$. Because the restriction of $\rho$ to $SO(2)$ is a direct sum of representations
of dimension 1, there are integers $n$ and $m$ such that the matrix of $\rho(r_\theta)$ in the basis $(x, \rho(s)x)$ of $\mathbb{C}^2$ is $\begin{pmatrix} e^{in\theta} & 0 \\ 0 & e^{-in\theta} \end{pmatrix}$. The equation $r_\theta s = sr_-\theta$ implies $m = -n$.

We verify that for every integer $n$, $\pi_n(s) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $\pi_n(r_\theta) = \begin{pmatrix} e^{in\theta} & 0 \\ 0 & e^{-in\theta} \end{pmatrix}$ defines a two-dimensional representation of $O(2)$. The representations $\pi_n$ and $\pi_{-n}$ are equivalent.

The only lines in $\mathbb{C}^2$ invariant under $\pi_n(s)$ are $\mathbb{C}(e_1 + e_2)$ and $\mathbb{C}(e_1 - e_2)$. These are invariant under $\pi_n(r_\theta)$ for every $\theta$ if and only if $n = 0$. We have $\pi_0 = \chi_1 \oplus \chi_1'$. For $n \geq 1$, $\pi_n$ is irreducible. The character $\chi_{\pi_n}$ of $\pi_n$ is such that

$$\chi_{\pi_n}(r_\theta) = 2 \cos n\theta, \quad \chi_{\pi_n}(s) = 0.$$

3. The Lie algebra of $O(2)$ is $\mathfrak{o}(2) = \mathfrak{so}(2)$, a real one-dimensional abelian Lie algebra. We can choose the basis $\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$ in $\mathfrak{o}(2)$ to identify $\mathfrak{o}(2)$ with $\mathbb{R}$. Thus $\text{Ad} : O(2) \rightarrow \text{GL}(\mathfrak{o}(2))$ is a representation of $O(2)$ of dimension 1. It must be equivalent to either $\chi_1$ or $\chi_1'$. We have $\text{Ad}_s : X \in \mathfrak{o}(2) \mapsto sXs^{-1} \in \mathfrak{o}(2)$ and

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix};$$

thus $\text{Ad}_s = -1$. Hence $\text{Ad} \sim \chi_1'$, the determinant representation.

4. Let $n \geq 1$ and $m \geq 1$ be integers. We have

$$\chi_{\pi_n} \otimes \chi_{\pi_m} = \chi_{\pi_n} \chi_{\pi_m}.$$

This character is zero on $s$ and satisfies

$$(\chi_{\pi_n} \chi_{\pi_m})(r_\theta) = 4 \cos n\theta \cos m\theta = 2(\cos(n + m)\theta + \cos(|n - m|\theta)).$$

If $n \neq m$, we find that

$$\chi_{\pi_n} \otimes \chi_{\pi_m} = \chi_{\pi_{n+m}} + \chi_{\pi_{|n-m|}},$$

whence

$$\pi_n \otimes \pi_m = \pi_{n+m} \oplus \pi_{|n-m|}.$$ 

If $n = m$, then $(\chi_{\pi_n} \chi_{\pi_n})(r_\theta) = \chi_{\pi_{2n}}(r_\theta) + 2$. The two-dimensional representation $\pi_0$ whose character takes the value 2 on $r_\theta$ and 0 on $s$ is reducible, with $\pi_0 = \chi_1 \oplus \chi_1'$. We then have

$$\pi_n \otimes \pi_n = \pi_{2n} \oplus \chi_1 \oplus \chi_1'.$$

5. (a) We set $c = r_{2\pi}$. We verify that $c$ and $s$ satisfy the relations $c^3 = I$, $s^2 = I$, and $c^2s = sc$. The subgroup $G$ of $O(2)$ generated by $c$ and $s$ is the group of six elements

$$\{e, c, c^2, s, sc, sc^2\}$$

isomorphic to $S_3$. 

(b) The representation $\sigma_n = \pi_n|_G$ decomposes as a direct sum of representations of $G \cong \mathfrak{S}_3$. We have

$$
\chi_{\sigma_n}(c) = 2 \cos \frac{2n\pi}{3} = \begin{cases} 
2 & \text{if } n \equiv 0 \pmod{3}, \\
-1 & \text{if } n \not\equiv 0 \pmod{3}.
\end{cases}
$$

On the other hand, the restriction of $\chi_1$ to $\mathfrak{S}_3$ is the trivial representation 1 while the restriction of $\chi'_1$ is the signature representation $\epsilon$. The restriction $\sigma_1$ of $\pi_1$ is the two-dimensional irreducible representation of $\mathfrak{S}_3$. One obtains the following character table:

<table>
<thead>
<tr>
<th></th>
<th>e</th>
<th>c</th>
<th>s</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>$\epsilon$</td>
<td>1</td>
<td>1</td>
<td>-1</td>
</tr>
<tr>
<td>$\sigma_1$</td>
<td>2</td>
<td>-1</td>
<td>0</td>
</tr>
<tr>
<td>$n \equiv 0 \pmod{3}$</td>
<td>2</td>
<td>2</td>
<td>0</td>
</tr>
<tr>
<td>$n \not\equiv 0 \pmod{3}$</td>
<td>2</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

Hence, for $k \in \mathbb{N}$, $\sigma_{3k} = 1 \oplus \epsilon, \sigma_{3k+1} = \sigma_{3k+2} = \sigma_1$.

**Geometric interpretation.** If $n \equiv 0 \pmod{3}$, the rotations $c = r_{\frac{2\pi}{3}}$ and $c^2 = r_{\frac{4\pi}{3}}$ act by $\pi_n$ as the identity on the plane $\mathbb{C}^2$. On the other hand, $\pi_n(s)$ always leaves invariant the line $D_1$ generated by the vector $e_1 + e_2$ and the line $D_2$ generated by the vector $e_1 - e_2$. More precisely $\pi_n(s)(e_1 + e_2) = e_1 + e_2$ and $\pi_n(s)(e_1 - e_2) = -(e_1 - e_2)$. Because these two lines are invariant under $\sigma_n$, we have

$$
\sigma_n|_{D_1} = 1 \quad \text{and} \quad \sigma_n|_{D_2} = \epsilon.
$$

If $n \not\equiv 0 \pmod{3}$, then $\sigma_n(c) = \pi_n(r_{\frac{2\pi}{3}})$ leaves none of the lines in $\mathbb{C}^2$ invariant. Thus $\sigma_n$ is a two-dimensional irreducible representation of $\mathfrak{S}_3$. This is the complexification of the representation of $\mathfrak{S}_3$ in $\mathbb{R}^2$ by the symmetries of an equilateral triangle centered at the origin: rotations through the angles $2\pi/3$ and $4\pi/3$ and symmetries with respect to the three altitudes.

### 3 Representations of the Dihedral and Quaternion Groups

Let $n$ be an integer, $n \geq 2$. We denote by $C_n$ the cyclic group of order $n$ and by $D_{(n)}$ the dihedral group of order $2n$. We know that

$$
C_n = \{I, r, r^2, \ldots, r^p, \ldots, r^{n-1}\},
$$

$$
D_{(n)} = \{I, r, r^2, \ldots, r^{n-1}, s, sr, sr^2, \ldots, sr^{n-1}\},
$$

where $r^n = I, s^2 = I,$ and $sr = r^{-1}$.

**Part I**

For $0 \leq k \leq n-1$, we denote by $\chi_k$ the character of $C_n$ such that

$$
\chi_k(r) = e^{\frac{2i\pi k}{n}}.
$$
1. What are the inequivalent irreducible representations of $C_n$?

2. Find the conjugacy classes of $D_{(n)}$. [Hint: Distinguish the case of $n$ odd from the case of $n$ even.]

3. Find the one-dimensional representations of $D_{(n)}$. 

   For each $k$, $0 \leq k \leq n - 1$, we consider the induced representation of the representation $\chi_k$ from $C_n$ to $D_{(n)}$, which we denote by $\rho_k$.

4. (a) Show that the representation $\rho_k$ is of dimension 2. Choose a basis of the vector space of this representation and write the matrix of $\rho_k(r)$ and the matrix of $\rho_k(s)$ in this basis.

   (b) Find the character of $\rho_k$.

5. (a) Show that $\rho_k$ and $\rho_{n-k}$ are equivalent. Is the representation $\rho_0$ irreducible? Show that if $n$ is even, with $n = 2m$, the representation $\rho_m$ is not irreducible.

   (b) Find the inequivalent irreducible representations of $D_{(n)}$.

---

**Part II**

In the group $O(2)$, each element can be written $r_\theta$ or $s_0r_\theta$, $0 \leq \theta < 2\pi$, with

$$r_\theta = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \quad \text{and} \quad s_0 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}.$$

We set

$$\hat{r}_\theta = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \quad \text{and} \quad \hat{s}_0 = \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.$$

6. (a) What is the geometric interpretation of $\hat{r}_\theta$ and of $\hat{s}_0$?

   (b) Show that there is a unique injective group morphism $\psi : O(2) \to SO(3)$ such that

   $$\psi(r_\theta) = \hat{r}_\theta \quad \text{and} \quad \psi(s_0) = \hat{s}_0.$$

   Let $\varphi$ be the projection (covering morphism) from $SU(2)$ onto $SO(3)$. We introduce the matrices $I = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, J = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$ and $K = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}.

7. (a) What is the inverse image under $\varphi$ of $\hat{r}_\theta$? of $\hat{s}_0$?

   (b) Show that $D_{(n)}$ can be identified with a subgroup of $O(2)$ generated by a rotation and $s_0$. What is the order of the group $\Gamma_n = \varphi^{-1}(\psi(D_{(n)}))$? What are the elements of this group?

8. Show that $\Gamma_2$ is the quaternion group,

   $$\{\pm I, \pm I, \pm J, \pm K\}.$$

9. Create the character table of the group $\Gamma_2$.

   Let $R^{(N)}$, where $N$ is a nonnegative integer, be the representation of $\Gamma_2$ obtained as the restriction to $\Gamma_2$ of the irreducible representation of dimension $N + 1$ of $SU(2)$. 

10. (a) Find the character of $R(N)$.
(b) Find the decomposition of $R(N)$ as a direct sum of irreducible representations of $\Gamma_2$.
(c) Same question for each of the representations $\rho \otimes R^{(1)}$, where $\rho$ is an irreducible representation of $\Gamma_2$.

Solutions

Part I

1. Because $C_n$ is an abelian group, all the irreducible representations of $C_n$ are one-dimensional. The group $C_n$ thus has $|C_n| = n$ inequivalent irreducible representations: these are the characters $\chi_k$, $0 \leq k \leq n - 1$, such that for $0 \leq p \leq n - 1$, $\chi_k(r^p) = e^{\frac{2\pi i kp}{n}}$.

2. From $sr^p s = r^{-1}$ we deduce the equation $sr = r^{-1}s$, whence for every integer $p$,

$$sr^p s = r^{-p}.$$ (i) Conjugacy classes of rotations. We deduce from the preceding formula that $r^p$ and $r^{n-p}$ are conjugate in $D(n)$. For $r^{p'}$ to be conjugate to $r^p$, it is necessary and sufficient that there be an integer $q$ such that $r^{p'} = sr^q r^p sr^{-q}$, which is equivalent to $r^{p'} = sr^p s$, or to $p + p' \equiv 0 \pmod{n}$.

- If $n$ is odd, $n = 2m + 1$, there are $m + 1 = \frac{n+1}{2}$ conjugacy classes of rotations,
  \[ \{1\}, \{r, r^{n-1}\}, \ldots, \{r^m, r^{m+1}\}. \]
- If $n$ is even, $n = 2m$, there are $m = \frac{n}{2} + 1$ conjugacy classes of rotations,
  \[ \{1\}, \{r, r^{n-1}\}, \ldots, \{r^{m-1}, r^{m+1}\}, \{r^m\}. \]

(ii) Conjugacy classes of symmetries. For $sr^{p'}$ to be conjugate to $sr^p$, it is necessary and sufficient that there be an integer $q$ such that $sr^{p'} = sr^q r^p r^{-q}$ or $sr^p = sr^q s r^{-q} s$. The first condition gives $p' - p + 2q \equiv 0 \pmod{n}$, and the second condition gives $p' + p - 2q \equiv 0 \pmod{n}$.

- If $n$ is odd, such a choice of $q$ is always possible. Thus there is only one conjugacy class of symmetries, \{s, sr, \ldots, sr^{n-1}\}.
- If $n$ is even, there are two conjugacy classes of symmetries, \{s, sr^2, \ldots, sr^{n-2}\} and \{sr, sr^3, \ldots, sr^{n-1}\}, each having $\frac{n}{2}$ elements.

To summarize, if $n$ is odd, there are $\frac{n+3}{2}$ conjugacy classes,

\[
\begin{array}{cccc}
(1) & (2) & (2) & (n) \\
1 & r & \ldots & r^{\frac{n-1}{2}} & s
\end{array}
\]

and if $n$ is even, there are $\frac{n}{2} + 3$ conjugacy classes,

\[
\begin{array}{cccc}
(1) & (2) & (2) & (\frac{n}{2}) & (\frac{n}{2}) \\
1 & r & \ldots & r^{\frac{n-1}{2}} & r_{\frac{n}{2}} & s & sr
\end{array}
\]

In both cases, we verify that there are $2n$ elements in the group $D(n)$. 

3. Let $\pi : D_{(n)} \to \mathbb{C}^*$ be a one-dimensional representation of $D_{(n)}$. Let $a = \pi(r)$ and $b = \pi(s)$. It must be true that

$$a^n = 1, \quad b^2 = 1, \quad bab = a^{-1}.$$  

Hence $a = \pm 1$ and $b = \pm 1$.

If $n$ is odd, we must have $a = +1$; there are two one-dimensional representations: the trivial representation $\pi_1$ and the representation $\pi'_1$ defined by

$$\pi'_1(r) = 1, \quad \pi'_1(s) = -1.$$  

If $n$ is even, there are four one-dimensional representations: $\pi_1$, $\pi'_1$, and $\pi_2$, $\pi'_2$ defined by

$$\pi_2(r) = -1, \quad \pi_2(s) = 1,$$

$$\pi'_2(r) = -1, \quad \pi'_2(s) = -1,$$

whence $\pi_2(r^p) = \pi'_2(r^p) = (-1)^p$, $\pi_2(sr^p) = (-1)^p$, $\pi'_2(sr^p) = (-1)^{p+1}$.

4. (a) By definition, the space $E_k$ of the representation $\rho_k$ is the vector space of maps $f$ of $D_{(n)}$ into $\mathbb{C}$ such that

$$\forall g \in D_{(n)}, \forall h \in C_n, \quad f(gh) = \chi_k(h^{-1})f(g),$$

i.e., $f( gr^p) = e^{-\frac{2i\pi kp}{n}} f(g)$, for $0 \leq p \leq n - 1$. Therefore

$$f( r^p) = e^{-\frac{2i\pi kp}{n}} f(I)$$

and

$$f( sr^p) = e^{-\frac{2i\pi kp}{n}} f(s),$$

and the function $f$ is entirely determined by $f(I)$ and $f(s)$, which are arbitrary complex numbers. Thus the representation $\rho_k$ is of dimension 2.

Let $f_1$ be the element of $E_k$ such that $f_1(I) = 1, f_1(s) = 0$ and let $f_2$ be the element of $E_k$ such that $f_2(I) = 0, f_2(s) = 1$. Then $(f_1, f_2)$ is a basis of $E_k$.

By definition, for $f \in E_k$ and $g_0, g \in D_{(n)}$,

$$(\rho_k(g_0)f)(g) = f(g_0^{-1}g),$$

whence

$$(\rho_k(r)f)(I) = f(r^{-1}) = \chi_k(r)f(I) = e^{\frac{2i\pi k}{n}} f(I),$$

$$(\rho_k(r)f)(s) = f(r^{-1}s) = f(sr) = \chi_k(r^{-1})f(s) = e^{-\frac{2i\pi k}{n}} f(s).$$

Thus $\rho_k(r) f_1 = e^{\frac{2i\pi k}{n}} f_1$ and $\rho_k(r) f_2 = e^{-\frac{2i\pi k}{n}} f_2$, whence the matrix of $\rho_k(r)$ in the basis $(f_1, f_2)$ of $E_k$ is given by

$$\rho_k(r) = \begin{pmatrix} e^{\frac{2i\pi k}{n}} & 0 \\ 0 & e^{-\frac{2i\pi k}{n}} \end{pmatrix}.$$
Similarly, \((\varrho_k(s)f)(I) = f(s)\) and \((\varrho_k(s)f)(s) = f(I)\), whence \(\varrho_k(s)f_1 = f_2\) and \(\varrho_k(s)f_2 = f_1\). Hence we have

\[
\varrho_k(s) = \begin{pmatrix}
0 & 1 \\
1 & 0
\end{pmatrix}.
\]

(b) We have

\[
\varrho_k(r^p) = \begin{pmatrix}
e^{\frac{2i\pi kp}{n}} & 0 \\
0 & e^{-\frac{2i\pi kp}{n}}
\end{pmatrix}
\]

and

\[
\varrho_k(sr^p) = \begin{pmatrix}
0 & e^{-\frac{2i\pi kp}{n}} \\
e^{\frac{2i\pi kp}{n}} & 0
\end{pmatrix}.
\]

The character of \(\varrho_k\) is thus given by

\[
\begin{cases}
\text{Tr}(\varrho_k(r^p)) = 2 \cos \frac{2kp\pi}{n}, & 0 \leq p \leq n - 1, \\
\text{Tr}(\varrho_k(sr^p)) = 0.
\end{cases}
\]

We verify that it takes the same value on each conjugacy class of \(D_n\).

5. (a) The representations \(\varrho_k\) and \(\varrho_{n-k}\) are inequivalent since they have same character.

The representation \(\varrho_0\) is not irreducible. In fact, \(\varrho_0 = \pi_1 \oplus \pi_1'\).

If \(n\) is even, \(n = 2m\), the character of \(\varrho_m\) takes the values \(2(-1)^p\) at \(r^p\) and 0 at \(sr^p\). We have \(\chi_{\rho_m} = \chi_{\pi_2} + \chi_{\pi_2'}\), whence \(\rho_m = \pi_2 \oplus \pi_2'\).

(b) (i) Case of odd \(n, n = 2m + 1\). The representations \(\rho_0, \rho_1, \ldots, \rho_{m-1}, \rho_m\) are inequivalent, since the values of their characters at \(r\) are different.

Each of the representations \(\rho_k, 1 \leq k \leq m\), is irreducible. In fact, if \(1 \leq k \leq m\), the only vector subspaces of \(E_k\) invariant under \(\rho_k(r)\) are the lines \(\mathbb{C}f_1\) and \(\mathbb{C}f_2\), and these are not invariant under \(\rho_k(s)\). [One can also show that the modulus of the character of each of these representations is equal to 1.]

The representations \(\pi_1, \pi_1', \rho_1, \ldots, \rho_m\) are \(2 + m = \frac{n+3}{2}\) inequivalent irreducible representations. This is the number of conjugacy classes of \(D_n\) for \(n\) odd. Thus we have determined all the irreducible representations of \(D_n\). [Another argument: the sum of the squares of the dimensions of these representations is \((\dim \pi_1)^2 + (\dim \pi_1')^2 + \sum_{k=1}^{m}(\dim \rho_k)^2 = 2 + 4m = 2n\), which is the order of \(D_n\).]

(ii) Case of even \(n, n = 2m\). The representations \(\rho_1, \ldots, \rho_{m-1}\) are inequivalent and irreducible (see the odd case).

The representations \(\pi_1, \pi_1', \pi_2, \pi_2', \rho_1, \ldots, \rho_{m-1}\) are \(4 + m - 1 = \frac{n}{2} + 3\) inequivalent irreducible representations, and this number is the number of conjugacy classes of \(D_n\) for even \(n\). We then have the complete list. [Another argument: the sum of the squares of the dimensions of these representations is \(4 + 4(m - 1) = 2n\), which is the order of \(D_n\).]
In both cases, the irreducible representations of \( D_{(n)} \) are one- or two-dimensional.

**Part II**

6. (a) The transformation \( \hat{r}_\theta \) of \( \mathbb{R}^3 \) is the rotation around the axis \( Oz \) and through an angle \( \theta \), \( \text{Rot}(e_3, \theta) \), and \( \hat{s}_0 \) is the symmetry with respect to the axis \( Ox, \text{Rot}(e_1, \pi) \).

(b) We see immediately that \( \hat{r}_\theta \) and \( \hat{s}_0 \) belong to \( \text{SO}(3) \). We set

\[
\psi(s_0 \hat{r}_\theta) = \hat{s}_0 \hat{r}_\theta.
\]

Thus we define an injective map from \( \text{O}(2) \) into \( \text{SO}(3) \). It is clear that

\[
\hat{r}_\theta \hat{s}_0 \hat{r}_\theta = \hat{s}_0 \hat{r}_\theta \hat{r}_\theta = \hat{s}_0 \hat{r}_\theta, \quad (\hat{s}_0)^2 = (\hat{s}_0^2) = I.
\]

The matrix product \( \hat{s}_0 \hat{r}_\theta \hat{s}_0 \) is equal to \( \hat{r}_\theta \). We deduce that \( \psi \) is a group morphism. In fact,

\[
\psi(r_\theta(s_0 r_\theta')) = \psi(s_0 r_{\theta' - \theta}) = \hat{s}_0 r_{\theta' - \theta},
\]

while

\[
\psi(r_\theta) \psi(s_0 r_\theta') = \hat{r}_\theta \hat{s}_0 \hat{r}_\theta' = \hat{s}_0 \hat{r}_\theta \hat{r}_\theta' = \hat{s}_0 r_{\theta' - \theta}.
\]

Similarly,

\[
\psi((s_0 r_\theta)(s_0 r_\theta')) = \psi(r_{\theta' - \theta}) = r_{\theta' - \theta},
\]

while

\[
\psi(s_0 r_\theta) \psi(s_0 r_\theta') = \hat{s}_0 \hat{r}_\theta \hat{s}_0 \hat{r}_\theta' = \hat{s}_0 r_{\theta' - \theta}.
\]

Geometrically, we associate to the rotation through an angle \( \theta \) in the plane \( xOy \) the rotation of \( \mathbb{R}^3 \) with the same angle and with axis \( Oz \), and to the symmetry \( s_0 \) of the plane \( xOy \) that exchanges the axes, the symmetry of \( \mathbb{R}^3 \) with respect to the axis \( x \). (While in \( \mathbb{R}^2 \) a symmetry with respect to a line has determinant \(-1\), a symmetry with respect to a line in \( \mathbb{R}^3 \) is a rotation through an angle \( \pi \), with determinant \(+1\).)

7. (a) We know that on the one hand, \( \varphi(\exp \frac{\theta}{2} \mathcal{K}) = \text{Rot}(e_3, \theta) = \hat{r}_\theta \), and on the other hand, \( \varphi(\exp \frac{\pi}{2} \mathcal{I}) = \text{Rot}(e_1, \pi) = \hat{s}_0 \). We then have

\[
\varphi^{-1}(\hat{r}_\theta) = \left\{ \exp \frac{\theta}{2} \mathcal{K}, -\exp \frac{\theta}{2} \mathcal{K} \right\},
\]

\[
\varphi^{-1}(\hat{s}_0) = \left\{ \exp \frac{\pi}{2} \mathcal{I}, -\exp \frac{\pi}{2} \mathcal{I} \right\}.
\]

We have \( \exp t \mathcal{I} = \cos t \mathcal{I} + \sin t \mathcal{I} \), whence \( \exp \frac{\pi}{2} \mathcal{I} = \mathcal{I} \). Thus

\[
\varphi^{-1}(\hat{s}_0) = \{ \mathcal{I}, -\mathcal{I} \}.
\]

Similarly, \( \exp t \mathcal{K} = \cos t \mathcal{I} + \sin t \mathcal{K} \), whence

\[
\varphi^{-1}(\hat{r}_\theta) = \left\{ \cos \frac{\theta}{2} \mathcal{I} + \sin \frac{\theta}{2} \mathcal{K}, -\cos \frac{\theta}{2} \mathcal{I} - \sin \frac{\theta}{2} \mathcal{K} \right\}.
\]

(b) The group \( D_{(n)} \) can be identified with the subgroup of \( \text{O}(2) \) generated by the rotation \( r_{\frac{2\pi}{n}} \) and the symmetry \( s_0 \).
The group $\psi(D_n)$ is of the same order as $D_n$, i.e., $2n$. The group $\Gamma_n = \varphi^{-1}(\psi(D_n))$ is of order $4n$, since for each element $g$ of $\psi(D_n)$, $\varphi^{-1}(g)$ contains two opposite elements of SU(2).

The group $\psi(D_n)$ is generated by $r_{2\pi/n}$ and $\hat{s}_0$. It consists of transformations of $\mathbb{R}^3$, $r_{2\pi/n}$ and $\hat{s}_0 r_{2\pi/n}$, for $0 \leq p \leq n - 1$. The group $\Gamma_n = \varphi^{-1}(\psi(D_n))$ is thus generated by the matrices of SU(2), $\pm (\cos \frac{p\pi}{n} I + \sin \frac{p\pi}{n} K)$, $I$, and $-I$. It consists of the matrices

$$
\cos \frac{p\pi}{n} I + \sin \frac{p\pi}{n} K, \quad -\cos \frac{p\pi}{n} I - \sin \frac{p\pi}{n} K,
$$

and the matrices

$$
\cos \frac{p\pi}{n} I - \sin \frac{p\pi}{n} J, \quad -\cos \frac{p\pi}{n} I + \sin \frac{p\pi}{n} J,
$$

for $0 \leq p \leq n - 1$.

8. If $n = 2$, the group $\Gamma_2 = \varphi^{-1}(\psi(D_2))$ consists of the matrices

$I$, $-I$, $\mathcal{I}$, $-\mathcal{I}$, $\mathcal{J}$, $-\mathcal{J}$, $\mathcal{K}$, $-\mathcal{K}$.

Therefore it is the quaternion group. We can study the case $n = 2$ directly. The group $D_2$ is the group $\{I, r, s, sr\}$, with $r^2 = s^2 = I$, $rs = sr$. It can be realized in $\mathbb{R}^2$ as the group

$$
\left\{ I, r_{\pi} = -I, \quad s_0 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad s_0 r_{\pi} = -s_0 \right\},
$$

and in $\mathbb{R}^3$ as the group

$$
\left\{ I, \quad \begin{pmatrix} -1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & 1 \end{pmatrix}, \quad \begin{pmatrix} 1 & 0 & 0 \\ 0 & -1 & 0 \\ 0 & 0 & -1 \end{pmatrix}, \quad \begin{pmatrix} -1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix} \right\}.
$$

We have $\varphi^{-1}(I) = \{I, -I\}$. (The letter $I$ sometimes denotes the identity on $\mathbb{R}^2$, sometimes the identity on $\mathbb{R}^3$ and sometimes the identity on $\mathbb{C}^2$.) On the other hand,

$$
\varphi^{-1}(r_{\pi}) = \{\mathcal{K}, -\mathcal{K}\},
$$

$$
\varphi^{-1}(s_0) = \{\mathcal{I}, -\mathcal{I}\},
$$

$$
\varphi^{-1}(s_0 r_{\pi}) = \{\mathcal{J}, -\mathcal{J}\}, \quad \text{because } \mathcal{K}\mathcal{I} = \mathcal{J}.
$$

Thus we obtain the list of elements of the group $\Gamma_2$.

9. We note that $\mathcal{I}^{-1} = -\mathcal{I}$, $\mathcal{J}^{-1} = -\mathcal{J}$, $\mathcal{K}^{-1} = -\mathcal{K}$.

The conjugacy classes of $\Gamma_2$ are

$$
\{I\}, \{-I\}, \{\mathcal{I}, \mathcal{I}^{-1}\}, \{\mathcal{J}, \mathcal{J}^{-1}\}, \{\mathcal{K}, \mathcal{K}^{-1}\}.
$$
In fact, $\mathcal{J}^{-1} = -\mathcal{J}^{-1} = -\mathcal{J}\mathcal{K} = -\mathcal{I}$, and $\mathcal{K}^{-1} = -\mathcal{K}\mathcal{K} = -\mathcal{I}$. These calculations show that $\mathcal{I}$, $\mathcal{J}$, $\mathcal{K}$ are pairwise not conjugate.

There are four one-dimensional representations of $\Gamma_2$. To show this, let $a$ and $b$ be the values of a one-dimensional representation $\chi$ of $\Gamma_2$ at $\mathcal{I}$ and $\mathcal{K}$ respectively. Then

$$a^2b^2 = 1 \quad \text{and} \quad a^2 = 1,$$

since

$$\mathcal{I}^2 = 1 \quad \text{and} \quad \mathcal{K}^{-1}\mathcal{I}\mathcal{K} = \mathcal{K}^{-1}\mathcal{I}\mathcal{J} = 1.$$

Thus $a = \pm 1$ and $b = \pm 1$. These choices determine the value of $\chi$ at $\mathcal{I}$ and at $-\mathcal{I} = \mathcal{I}^2$.

Because this group has five conjugacy classes, there is another irreducible representation, $\alpha$, of dimension $d \geq 2$. We must have $4 + d^2 = |\Gamma_2|$. Because the order of $\Gamma_2$ is 8, necessarily $d = 2$. We complete the character table using the orthogonality of columns. The representation $\alpha$ is in fact the fundamental representation of $\Gamma_2 \subset \text{SU}(2)$. One obtains the table

<table>
<thead>
<tr>
<th></th>
<th>(1)</th>
<th>(1)</th>

</table>

(We have used the same letter to denote the representation and its character.)

10. (a) Let $\chi^{(N)}$ be the character of the irreducible representation of dimension $N + 1$ of $\text{SU}(2)$. We have $\chi^{(N)}(I) = N + 1$.

We know that if $g \in \text{SU}(2)$ is conjugate to $\left( \begin{array}{cc} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{array} \right)$, $0 < \theta < \pi$, then

$$\chi^{(N)}(g) = \sum_{m=-N}^{N} e^{2im\theta} \frac{\sin(N+1)\theta}{\sin \theta}.$$

Since $\mathcal{I}$, $\mathcal{J}$, and $\mathcal{K}$ are conjugate in $\text{SU}(2)$ to the matrix $\left( \begin{array}{cc} e^{i\pi/2} & 0 \\ 0 & e^{-i\pi/2} \end{array} \right)$, we have

$$\chi^{(N)}(\mathcal{I}) = \chi^{(N)}(\mathcal{J}) = \chi^{(N)}(\mathcal{K}) = \sin(N+1)\frac{\pi}{2} = \cos N\frac{\pi}{2}.$$

Thus we obtain

$$\chi^{(N)}(\mathcal{I}) = 0, \text{ if } N \text{ is odd},$$

$$\chi^{(N)}(\mathcal{I}) = 1, \text{ if } N \equiv 0 \pmod{4},$$

$$\chi^{(N)}(\mathcal{I}) = -1, \text{ if } N \equiv 2 \pmod{4}.$$
We have \(-I = \begin{pmatrix} -1 & 0 \\ 0 & -1 \end{pmatrix} = \begin{pmatrix} e^{i\pi} & 0 \\ 0 & e^{-i\pi} \end{pmatrix}\). If \(N\) is even, \(N = 2N'\),

\[
\chi^{(N)}(-I) = \sum_{m=-N'}^{N'} e^{2im\pi} = 2N' + 1 = N + 1,
\]

while if \(N\) is odd, \(N = 2N' + 1\), the index \(m\) takes half-integer values, and thus each of the \(N + 1\) terms of the sum is equal to \(e^{-i\pi} = -1\), and we obtain

\[
\chi^{(N)}(-I) = -(N + 1).
\]

Hence

\[
\chi^{(N)}(-I) = (-1)^N (N + 1).
\]

(b) In order to find the decomposition of \(R^{(N)}\) as a direct sum of irreducible representations, we calculate \((\alpha_i \mid \chi^{(N)})\), \(0 \leq i \leq 3\), and \((\alpha \mid \chi^{(N)})\). We have

\[
(\alpha_0 \mid \chi^{(N)}) = \frac{1}{8}(\chi^{(N)} - I) + 6\chi^{(N)}(I),
\]

\[
(\alpha_i \mid \chi^{(N)}) = \frac{1}{8}(\chi^{(N)} - I) - 2\chi^{(N)}(I), \quad 1 \leq i \leq 3,
\]

\[
(\alpha \mid \chi^{(N)}) = \frac{1}{4}(\chi^{(N)} - I - \chi^{(N)}(I)).
\]

If \(N\) is odd, then \((\alpha_i \mid \chi^{(N)}) = 0\), for \(0 \leq i \leq 3\), and \((\alpha \mid \chi^{(N)}) = \frac{1}{2}(N + 1)\), whence

\[
R^{(N)} = \frac{N + 1}{2}\alpha.
\]

In particular, \(R^{(1)} = \alpha\).

If \(N\) is even and \(N \equiv 0 \pmod{4}\), then \((\alpha_0 \mid \chi^{(N)}) = \frac{N}{4} + 1\), \((\alpha_i \mid \chi^{(N)}) = \frac{N}{4}\) for \(1 \leq i \leq 3\), and \((\alpha \mid \chi^{(N)}) = 0\), whence

\[
R^{(N)} = \left(\frac{N}{4} + 1\right)\alpha_0 \oplus \frac{N}{4}(\alpha_1 \oplus \alpha_2 \oplus \alpha_3).
\]

If \(N\) is even and \(N \equiv 2 \pmod{4}\), then \((\alpha_0 \mid \chi^{(N)}) = \frac{1}{8}(2(N + 1) - 6) = \frac{N - 2}{4}\),

\[
(\alpha_i \mid \chi^{(N)}) = \frac{1}{8}(2(N + 1) + 2) = \frac{N + 2}{4}
\]

for \(1 \leq i \leq 3\), and \((\alpha \mid \chi^{(N)}) = 0\), whence

\[
R^{(N)} = \frac{N - 2}{4}\alpha_0 \oplus \frac{N + 2}{4}(\alpha_1 \oplus \alpha_2 \oplus \alpha_3).
\]

We verify that in each case, the dimension of \(R^{(N)}\) is \(N + 1\).

(c) We have \(R^{(1)} = \alpha\). It is clear that \(\alpha_0 \otimes \alpha = \alpha\). By calculating the scalar products of the characters, we obtain \(\alpha_i \otimes \alpha = \alpha\), for \(0 \leq i \leq 3\), and

\[
\alpha \otimes \alpha = \alpha_0 \oplus \alpha_1 \oplus \alpha_2 \oplus \alpha_3.
\]
The preceding results can be generalized to the subgroups \( \varphi^{-1}(\psi(D_{(n)})) \), \( n > 2 \), and more generally, to the finite subgroups of SU(2). These either are of the form \( \varphi^{-1}(G) \), for a finite subgroup \( G \) of SO(3), or are cyclic groups of odd order. For each finite subgroup of SU(2), one can decompose each tensor product of an irreducible representation and the restriction of the two-dimensional representation of SU(2) into a direct sum of irreducible representations. One can show that the matrix of coefficients appearing in these decompositions can be calculated from a matrix, called the Cartan matrix, associated to a simple Lie algebra. The correspondence between finite subgroups of SU(2) and simple Lie algebras is called the \textit{McKay correspondence}. See B. Kostant, “The McKay correspondence, the Coxeter element and representation theory,” in Élie Cartan et les mathématiques d’aujourd’hui. The Mathematical Heritage of Élie Cartan, Astérisque, hors série, Société Mathématique de France, 1985, pp. 209–255, and “The Coxeter element and the branching law for the finite subgroups of SU(2),” in The Coxeter Legacy. Reflections and Projections, C. Davis and E. W. Ellers, eds., American Mathematical Society, Providence, RI, 2006, pp. 63–70.

4 Representations of SU(2) and of \( \mathfrak{S}_3 \)

We denote by \( \sigma \) the fundamental representation of SU(2) in \( \mathbb{C}^2 \), and by \((u_0, u_1)\) the canonical basis of \( \mathbb{C}^2 \).

Let \( u_{k\ell m} = u_k \otimes u_\ell \otimes u_m \), where \( k, \ell, m = 0 \) or \( 1 \), be the vectors of the canonical basis of the vector space \( E = \mathbb{C}^2 \otimes \mathbb{C}^2 \otimes \mathbb{C}^2 \).

1. Show that \( \sigma \) is equivalent to \( D_{1/2} \). Find an isomorphism of \( \mathbb{C}^2 \) onto the support \( V_{1/2} \) of the representation \( D_{1/2} \) that intertwines \( \sigma \) and \( D_{1/2} \).

2. Decompose the representation \( \rho = \sigma \otimes \sigma \otimes \sigma \) of SU(2) in \( E \) into a direct sum of irreducible representations.

3. Let \( D\rho \) be the differential of the representation \( \rho \). Set

\[
\xi_3 = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 0 & -i \end{pmatrix} \in \mathfrak{su}(2).
\]

Is each \( u_{k\ell m} \) an eigenvector of \( (D\rho)(\xi_3) \)? Find the eigenvalues of \( (D\rho)(\xi_3) \) and the multiplicity of each one.

4. Let \( \mathfrak{S}_3 \) be the symmetric group on three elements.

(a) Give the list of inequivalent irreducible representations and the character table of \( \mathfrak{S}_3 \).

(b) We define a representation \( \pi \) of \( \mathfrak{S}_3 \) in \( E \) by

\[
\pi(g)(u_{k\ell m}) = u_{g^{-1}(k)g^{-1}(\ell)g^{-1}(m)};
\]

for \( g \in \mathfrak{S}_3 \). Find the character of \( \pi \) and decompose \( \pi \) as a direct sum of irreducible representations.

5. Find a basis of each of the isotypic components of \((E, \pi)\).
6. Show that each isotypic component of \((E, \pi)\) is the support of a representation of \(SU(2)\) and find the representation. Find a basis of \(E\) adapted to the decomposition of the representation \(\rho\) of \(SU(2)\) into irreducible representations.

**Solutions**

1. Because \(\sigma\) is two-dimensional, in order to show that \(\sigma\) is equivalent to \(D^{\frac{1}{2}}\), it suffices to show that \(\sigma\) is irreducible. In fact, the eigenspaces of \(g_t = \begin{pmatrix} e^{i\theta} & 0 \\ 0 & e^{-i\theta} \end{pmatrix}\) are \(\mathbb{C}u_0\) and \(\mathbb{C}u_1\), and these lines are not invariant under \(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}\) \(\in SU(2)\).

By definition, if \(g = \begin{pmatrix} a & b \\ \bar{b} & \bar{a} \end{pmatrix}\) \(\in SU(2)\), then

\[
\sigma(g)u_0 = au_0 - \bar{b}u_1, \quad \sigma(g)u_1 = bu_0 + \bar{a}u_1,
\]

while

\[
(D^{\frac{1}{2}}(g)f)(z_1, z_2) = f(\bar{a}z_1 - bz_2, \bar{b}z_1 + az_2)
\]

and \(f^{\frac{1}{2}}(z_1, z_2) = z_1, \quad f^{-\frac{1}{2}}(z_1, z_2) = z_2\). Thus

\[
D^{\frac{1}{2}}(g)f^{\frac{1}{2}} = \bar{a}f^{\frac{1}{2}} - bf^{-\frac{1}{2}}, \quad D^{\frac{1}{2}}(g)f^{-\frac{1}{2}} = \bar{b}f^{\frac{1}{2}} + af^{-\frac{1}{2}}.
\]

The isomorphism \(T\) of \(\mathbb{C}^2\) onto \(V^{\frac{1}{2}}\) defined by

\[
T(u_0) = f^{\frac{1}{2}}, \quad T(u_1) = -f^{-\frac{1}{2}}
\]

intertwines \(\sigma\) and \(D^{\frac{1}{2}}\). This can be easily verified by calculating \(D^{\frac{1}{2}}(g)T(u_k)\) and \(T(\sigma(g)u_k)\), for \(k = 0\) and 1.

2. Because the representation \(\sigma\) is equivalent to \(D^{\frac{1}{2}}\), \(\rho = \sigma \otimes \sigma \otimes \sigma\) is equivalent to \(D^{\frac{1}{2}} \otimes D^{\frac{1}{2}} \otimes D^{\frac{1}{2}}\). We can thus apply the Clebsch–Gordan formula, which yields \(D^{\frac{1}{2}} \otimes D^{\frac{1}{2}} = D^0 \oplus D^1\), \(D^0\) being the trivial one-dimensional representation. Thus

\[
\rho = (D^0 \oplus D^1) \otimes D^{\frac{1}{2}} = D^{\frac{1}{2}} \oplus (D^1 \otimes D^{\frac{1}{2}}).
\]

Because \(D^1 \otimes D^{\frac{1}{2}} = D^{\frac{3}{2}} \oplus D^{\frac{1}{2}}\), we obtain

\[
\rho = 2D^{\frac{1}{2}} \oplus D^{\frac{3}{2}}.
\]

3. Because \(\rho = \sigma \otimes \sigma \otimes \sigma\), for \(X \in su(2)\), we have

\[
(D\rho)(X)u_{k\ell m} = (D\sigma)(X)u_k \otimes u_\ell \otimes u_m + u_k \otimes (D\sigma)(X)u_\ell \otimes u_m + u_k \otimes u_\ell \otimes (D\sigma)(X)u_m.
\]

If \(X = \xi_3\), we have \((D\sigma)(\xi_3)u_k = \xi_3 u_k = (-1)^k i^{\frac{k}{2}} u_k\), whence

\[
(D\rho)(\xi_3)u_{k\ell m} = ((-1)^k + (-1)^\ell + (-1)^m) i^{\frac{k}{2}} u_{k\ell m}.
\]

Thus each \(u_{k\ell m}\) is an eigenvector of \((D\rho)(\xi_3)\).
The eigenvalues are
\[ \frac{3i}{2}, -\frac{3i}{2}, \frac{i}{2}, -\frac{i}{2} \]
with the eigenvectors \( u_{000} \) for \( 3i/2 \); \( u_{111} \) for \( -3i/2 \); \( u_{001}, u_{010}, \) and \( u_{110} \) for \( i/2 \); \( u_{011}, u_{101}, \) and \( u_{110} \) for \( -i/2 \). Thus \( 3i/2 \) and \( -3i/2 \) are simple, while \( i/2 \) and \( -i/2 \) have multiplicity 3.

4. (a) We know that \( S_3 \) has two irreducible one-dimensional representations, the trivial representation \( 1 \) and the signature representation \( \epsilon \), and a two-dimensional irreducible representation, \( \alpha \). The conjugacy class of a cyclic permutation \( c \) contains two elements (the two cyclic permutations different from the identity), and the conjugacy class of a transposition \( t \) contains three elements (the three transpositions). Thus the character table is

<table>
<thead>
<tr>
<th></th>
<th>(1)</th>
<th>(2)</th>
<th>(3)</th>
</tr>
</thead>
<tbody>
<tr>
<td>( e )</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>( c )</td>
<td>1</td>
<td>1</td>
<td>-1</td>
</tr>
<tr>
<td>( t )</td>
<td>2</td>
<td>-1</td>
<td>0</td>
</tr>
</tbody>
</table>

(b). The group \( S_3 \) acts on ordered triples \((k, \ell, m)\) by permutations. The trace \( \chi_\pi(g) \) of \( \pi(g) \) is the number of triples that are invariant under the action of \( g^{-1} \). We have \( \chi_\pi(e) = 8 \). If \( g \) is a cyclic permutation, only \( u_{000} \) and \( u_{111} \) are invariant, and thus \( \chi_\pi(c) = 2 \). If \( t \) is a transposition, then \( \chi_\pi(t) = 4 \). In fact, \( t = (12) \) leaves \( u_{000}, u_{111}, u_{001}, u_{110} \) invariant.

We find the decomposition of \( \pi = m_1 1 \oplus m_\epsilon \epsilon \oplus m_\alpha \alpha \) by calculating, by means of the character table,

\[ m_1 = (\chi_1|\chi_\pi) = 4, \quad m_\epsilon = (\chi_\epsilon|\chi_\pi) = 0, \quad m_\alpha = (\chi_\alpha|\chi_\pi) = 2. \]

Thus \( \pi = 4 1 \oplus 2 \alpha \).

5. We have seen that \( E = 4E_1 \oplus 2E_\alpha \). We denote by \( V_1 = 4E_1 \) and \( V_\alpha = 2E_\alpha \) the isotypic components of \( E \). Thus \( E = V_1 \oplus V_\alpha \).

The projection of \( E \) onto \( V_1 \) is defined by

\[ P_1 u_{k\ell m} = \frac{1}{6} \sum_{g \in S_3} \pi(g) u_{k\ell m} = \frac{1}{6} \sum_{g \in S_3} u_{g(k)g(\ell)g(m)}. \]

We obtain

\[ P_1 u_{000} = u_{000}, \quad P_1 u_{111} = u_{111}, \]
\[ P_1 u_{001} = P_1 u_{010} = P_1 u_{100} = \frac{1}{3} (u_{001} + u_{010} + u_{100}) = u, \]
\[ P_1 u_{011} = P_1 u_{101} = P_1 u_{110} = \frac{1}{3} (u_{011} + u_{101} + u_{110}) = u'. \]

A basis of \( V_1 = 4E_1 \) is thus \((u_{000}, u_{111}, u, u')\).
For the projection onto $V^\alpha$, we obtain

$$P_\alpha u_{k\ell m} = \frac{1}{3} (2u_{k\ell m} - u_{\ell mk} - u_{m\ell k}).$$

Thus $P_\alpha u_{000} = P_\alpha u_{111} = 0$ and

$$P_\alpha u_{001} = \frac{1}{3} (2u_{001} - u_{100} - u_{010}) = v, \quad P_\alpha u_{100} = \frac{1}{3} (2u_{100} - u_{010} - u_{001}) = v',
\quad P_\alpha u_{110} = \frac{1}{3} (2u_{110} - u_{011} - u_{101}) = w, \quad P_\alpha u_{011} = \frac{1}{3} (2u_{011} - u_{101} - u_{110}) = w',
$$

and

$$P_\alpha u_{101} = -P_\alpha (u_{001} + u_{100}), \quad P_\alpha u_{010} = -P_\alpha (u_{110} + u_{011}).$$

A basis of $V^\alpha = E^\alpha \oplus E^\alpha$ is thus given by the four vectors $v, v', w, w'$.

We can also obtain this result by observing that $V^\alpha$ is the orthogonal complement of $V_1$ for the scalar product on $E$ such that the vectors $u_{k\ell m}$ form an orthonormal basis.

Set $\jmath = e^{2\pi i/3}$, so that $\jmath^2 + \jmath + 1 = 0$. We see that vectors $x = (j+2)v + (2j+1)v' = u_{001} + j u_{100} + j^2 u_{010}$ and $y = (j-1)v - (j+2)v' = u_{010} + j u_{001} + j^2 u_{100}$, on the one hand, and vectors $x' = (j+2)w + (2j+1)w' = u_{110} + j u_{011} + j^2 u_{101}$ and $y' = (j-1)w - (j+2)w' = u_{101} + j u_{110} + j^2 u_{011}$, on the other hand, form a basis of a vector space $E^\alpha$, the support of the representation $\alpha$ of $S_3$.

6. Let us show that the subspace $V_\perp$ is closed under the representation $D\rho$ of $su(2)$, and thus under the representation $\rho$ of $SU(2)$, which is connected. For convenience we denote $(D\rho)(X)u_{k\ell m}$ by $X \cdot u_{k\ell m}$, for $X \in su(2)$. The four vectors of the basis given above are eigenvectors of $(D\rho)(\xi_3)$,

$$\xi_3 \cdot u_{000} = \frac{3i}{2} u_{000}, \quad \xi_3 \cdot u_{111} = -\frac{3i}{2} u_{111}, \quad \xi_3 \cdot u = \frac{i}{2} u, \quad \xi_3 \cdot u' = -\frac{i}{2} u'.
$$

On the other hand,

$$(D\sigma)(\xi_1)u_0 = \frac{i}{2} u_1, \quad (D\sigma)(\xi_1)u_1 = \frac{i}{2} u_0,
\quad (D\sigma)(\xi_2)u_0 = \frac{1}{2} u_1, \quad (D\sigma)(\xi_2)u_1 = \frac{1}{2} u_0.$$

Thus,

$$\xi_1 \cdot u_{000} = \frac{3i}{2} u, \quad \xi_1 \cdot u_{111} = \frac{3i}{2} u', \quad \xi_1 \cdot u = \frac{i}{2} (u_{000} + 2u') \in V_\perp,
$$

and similarly, $\xi_1 \cdot u' = \frac{i}{2} (u_{111} + 2u) \in V_\perp$. Furthermore,

$$\xi_2 \cdot u_{000} = \frac{3}{2} u, \quad \xi_2 \cdot u_{111} = \frac{3}{2} u', \quad \xi_2 \cdot u = -\frac{1}{2} (u_{000} - 2u') \in V_\perp,
$$

and similarly, $\xi_2 \cdot u' = \frac{1}{2} (u_{111} - 2u) \in V_\perp.$
The restriction of $D\rho$ to $V^\perp$ is a representation of dimension 4 of $su(2)$ in which $\xi_3$ has eigenvalue $3i/2$. We know that this property implies that $\rho|_{V^\perp}$ is equivalent to $D_3^\perp$.

We verify that $T : V^\perp \rightarrow V^\perp \cong E^\perp$, defined by $T(u_{000}) = -\frac{3}{2}f_{-\frac{1}{2}}$, $T(u_{111}) = \frac{3}{2}f_{\frac{1}{2}}$, $Tu' = -\frac{3}{2}f_{\frac{1}{2}}$, intertwines $D\rho|_{V^\perp}$ and $D_3^\perp$.

Next we consider the space $V^\alpha = 2E^\alpha$. We have

$$\xi_3 \cdot v = \frac{i}{2}v, \quad \xi_3 \cdot v' = \frac{i}{2}v', \quad \xi_3 \cdot w = -\frac{i}{2}w, \quad \xi_3 \cdot w' = -\frac{i}{2}w'.$$

The vector subspace generated by $v$ and $w$ is the support of a representation $D_1^\perp$. In fact, it is closed under $D\rho$. We have $\xi_1 \cdot v = -\frac{i}{2}w$ and $\xi_1 \cdot w = -\frac{i}{2}v$, because $\xi_1^2 = -\frac{1}{4}I$. Furthermore, $\xi_2 \cdot v = -\frac{1}{2}w$ and $\xi_2 \cdot w = \frac{1}{2}v$.

We verify that if we set $Tv = f_{-\frac{1}{2}}$ and $Tw = f_{\frac{1}{2}}$, the isomorphism $T$ intertwines the restriction of $D\rho$ to the vector space generated by $v$ and $w$ with $D_1^\perp$.

Analogous equations for $v'$ and $w'$ show that the vector subspace generated by $v'$ and $w'$ is also the support of a representation $D_1^\perp$. In conclusion, the two vector subspaces generated by $v$ and $w$ on the one hand, and by $v'$ and $w'$ on the other hand, are each the support of a representation $D_1^\perp$.

Using the decomposition of $E$ under the action of $S_3$, we have obtained a basis of $E$ adapted to the decomposition of $\rho = \sigma \otimes \sigma \otimes \sigma$.

We see that the isotypic components in the decompositions of the representation $\rho$ of $SU(2)$ and of the representation $\pi$ of $S_3$ correspond to one another: $V^\perp = 4E^\perp \cong E^\perp$ and $V^\alpha = 2E^\alpha \cong 2E^\perp$. We have proved

$$E = (\dim E^\alpha)E^\perp \oplus (\dim E^\perp)E^\alpha = (\dim E^\perp)E^\alpha \oplus (\dim E^\perp)E^\perp.$$

The fact that $\rho = \bigoplus_{k \in I} p_k \rho_k = \bigoplus_{k \in I} m_k \pi_k$, where the $p_k$ are irreducible representations of $SU(2)$ and the $\pi_k$ irreducible representations of $S_3$, with $p_k = \dim \pi_k$ and $m_k = \dim \rho_k$, is a particular case of a general property, the Schur–Weyl duality between representations of $GL(V)$ and of $S_r$ on $V^{\otimes r}$, for a given vector space $V$ and a positive integer $r$ (here $V = \mathbb{C}^2$ and $r = 3$). See Goodman–Wallach (1998).

5 Pseudo-unitary and Pseudo-orthogonal Groups

We consider the Lie group

$$SU(1, 1) = \{ A \in SL(2, \mathbb{C}) \mid AJ^t A = J\}, \quad \text{where} \quad J = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

1. Show that $A \in SU(1, 1)$ if and only if $A = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$, where $a$ and $b$ are complex numbers such that $|a|^2 - |b|^2 = 1$.

Is the Lie group $SU(1, 1)$ compact?
2. For \( g \in \text{SL}(2, \mathbb{R}) \), we set \( \mu(g) = \tau g \tau^{-1} \), where \( \tau = (\begin{smallmatrix} 1 & i \\ i & 1 \end{smallmatrix}) \). What is the image of \( \mu \)? Show that the Lie groups \( \text{SU}(1, 1) \) and \( \text{SL}(2, \mathbb{R}) \) are isomorphic.

3. Let \( \xi_1 = \frac{1}{2} (0 \ i \ i \ 0) \), \( \xi_2 = \frac{1}{2} (0 \ -1 \ 1 \ 0) \), \( \xi_3 = \frac{1}{2} (i \ 0 \ 0 \ -i) \). Show that the matrices \( M_1 = -i \xi_1, M_2 = -i \xi_2, M_3 = \xi_3 \) form a basis of the Lie algebra \( \mathfrak{su}(1, 1) \) of \( \text{SU}(1, 1) \). Write the commutation relations of \( \mathfrak{su}(1, 1) \) in this basis.

On \( \mathbb{R}^3 \) we consider the quadratic form defined by \( Q(x) = x_1^2 + x_2^2 - x_3^2 \), where \( x_1, x_2, x_3 \) denote the components of \( x \in \mathbb{R}^3 \) in the canonical basis \((e_1, e_2, e_3)\).

4. Define an isomorphism \( \alpha \) from \( \mathbb{R}^3 \) onto \( \mathfrak{su}(1, 1) \) by setting

\[
\alpha(e_k) = M_k, \ k = 1, 2, 3.
\]

(a) For each \( x \in \mathbb{R}^3 \), calculate the determinant of \( \alpha(x) \) and compare it to \( Q(x) \).

(b) Denote by \( K \) the Killing form of \( \mathfrak{su}(1, 1) \). Show that for every \( x \in \mathbb{R}^3 \),

\[
K(\alpha(x), \alpha(x)) = 2Q(x).
\]

Consider the Lie group

\[
O(2, 1) = \{ A \in \text{GL}(3, \mathbb{R}) \mid AJ_{21}^t A = J_{21} \}, \quad \text{where} \quad J_{21} = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & -1 \end{pmatrix}.
\]

Let \( \text{SO}(2, 1) = O(2, 1) \cap \text{SL}(3, \mathbb{R}) \), and let \( \text{SO}_0(2, 1) \) be the connected component of the identity of \( \text{SO}(2, 1) \).

5. Let \( A \in \text{GL}(3, \mathbb{R}) \). Show that \( A \in O(2, 1) \) if and only if for every \( x \in \mathbb{R}^3 \),

\[
Q(Ax) = Q(x).
\]

Find a basis of the Lie algebra \( \mathfrak{so}(2, 1) \) of \( \text{SO}(2, 1) \). Write the commutation relations of \( \mathfrak{so}(2, 1) \) in this basis.

What can one say about the Lie algebra of \( \text{O}(2, 1) \)?

6. Are the Lie algebras \( \mathfrak{su}(1, 1) \) and \( \mathfrak{so}(2, 1) \) isomorphic? Are the Lie algebras \( \mathfrak{sl}(2, \mathbb{R}) \) and \( \mathfrak{so}(2, 1) \) isomorphic?

8. Consider the adjoint representation \( \text{Ad} \) of the group \( \text{SU}(1, 1) \) on its Lie algebra. To \( g \in \text{SU}(1, 1) \) we associate the matrix \( \psi(g) \) of \( \text{Ad}_g \) in the basis \((M_1, M_2, M_3)\) of \( \mathfrak{su}(1, 1) \). It is known that \( \text{SU}(1, 1) \) is connected.

(a) Show that for every \( g \in \text{SU}(1, 1) \), \( \psi(g) \in \text{O}(2, 1) \).

(b) Show that \( \psi \) is a Lie group morphism from \( \text{SU}(1, 1) \) to \( \text{SO}_0(2, 1) \). What is the kernel of \( \psi \)?

(c) Find the differential of \( \psi \). Show that \( \psi \) is surjective from \( \text{SU}(1, 1) \) onto \( \text{SO}_0(2, 1) \).
Solutions

1. The condition \( AJ ^t \bar{A} = J \) can be written

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix} \begin{pmatrix} \bar{a} & \bar{c} \\ \bar{b} & \bar{d} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix},
\]

which is equivalent to \( a\bar{a} - b\bar{b} = 1, \ c\bar{c} - d\bar{d} = -1, \ a\bar{c} - b\bar{d} = 0, \ \bar{a}c - \bar{b}d = 0 \). We deduce that \( ac\bar{c} - bc\bar{d} = 0 \). Because \( ad - bc = 1 \), we have \( ac\bar{c} - ad\bar{d} + \bar{d} = 0 \), whence \( d = \bar{a} \) and \( c = \bar{b} \). Thus \( A = \begin{pmatrix} a & \bar{b} \\ \bar{a} & b \end{pmatrix} \), and the condition \( \det A = 1 \) is equivalent to \( |a|^2 - |b|^2 = 1 \).

To show that the Lie group \( SU(1,1) \) is not compact, it suffices to show that the set \( \{(a,b) \in \mathbb{C}^2 \mid |a|^2 - |b|^2 = 1\} \) is not bounded; it contains, for example, all pairs of positive reals of the form \( (\sqrt{x^2+1}, x) \).

2. If \( \tau = \begin{pmatrix} 1 & i \\ i & 1 \end{pmatrix} \), then \( \tau^{-1} = \frac{1}{2} \begin{pmatrix} 1 & -i \\ -i & 1 \end{pmatrix} \). Let \( g = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in SL(2, \mathbb{R}) \). Then \( \mu(g) \) is the matrix

\[
\tau g \tau^{-1} = \begin{pmatrix} a & b \\ c & d \end{pmatrix} = \frac{1}{2} \begin{pmatrix} \alpha + \delta - i(\beta - \gamma) & \beta + \gamma - i(\alpha - \delta) \\ \beta + \gamma + i(\alpha - \delta) & \alpha + \delta + i(\beta - \gamma) \end{pmatrix},
\]

We verify that \( d = \bar{a}, c = \bar{b} \), and \( |a|^2 - |b|^2 = \alpha \delta - \beta \gamma = 1 \) because \( g \in SL(2, \mathbb{R}) \). Furthermore, \( \det \mu(g) = \det g = 1 \). Thus the image of \( \mu \) is contained in \( SU(1,1) \).

On the other hand, if \( h = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in SU(1,1), \) we have

\[
\tau^{-1} h \tau = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} = \frac{1}{2} \begin{pmatrix} a + d + i(b - c) & b + c + i(a - d) \\ b + c - i(a - d) & a + d - i(b - c) \end{pmatrix}.
\]

We see that under the hypothesis \( d = \bar{a} \) and \( c = \bar{b} \), the numbers \( \alpha, \beta, \gamma, \) and \( \delta \) are real. Furthermore, because \( h \in SU(1,1), \)

\[
\det(\tau^{-1} h \tau) = \det h = 1.
\]

Thus \( \mu \) is a bijection of \( SL(2, \mathbb{R}) \) onto \( SU(1,1) \). Furthermore, \( \mu \) is a group morphism since \( \mu(gg') = \mu(g)\mu(g') \) for every \( g \) and \( g' \in SL(2, \mathbb{R}) \). Finally, the coefficients of \( \mu(g) \) are linear functions and thus are continuous in the coefficients of \( g \). Thus \( \mu \) is a Lie group isomorphism of \( SL(2, \mathbb{R}) \) onto \( SU(1,1) \).

3. Let \( M \) be a matrix of \( gl(2, \mathbb{C}) \). By differentiating both sides of the equation

\[
\exp(sM)J \exp(s^t \bar{M}) = J
\]

with respect to \( s \in \mathbb{R}, \) we obtain

\[
\exp(sM)(MJ + J^t \bar{M}) \exp(s^t \bar{M}) = 0.
\]

By evaluating at \( s = 0, \) we see that in order for \( \exp(sM) \) to belong to \( SU(1,1) \) for every \( s \in \mathbb{R} \), we must have \( MJ + J^t \bar{M} = 0 \). And conversely, if the condition \( MJ + J^t \bar{M} = 0 \) is satisfied, the matrix \( \exp(sM)J \exp(s^t \bar{M}) \) is constant and
equal to its initial value, which is $J$. On the other hand, the condition $\text{Tr}M = 0$ is equivalent to $\text{Det}(\exp sM) = 1$, for every $s$. Hence the Lie algebra of $\text{SU}(1, 1)$ is

$$\mathfrak{su}(1, 1) = \{M \in \mathfrak{sl}(2, \mathbb{C}) \mid MJ + J \, ^t \!M = 0\}.$$ 

The matrices of $\mathfrak{su}(1, 1)$ are of the form $\begin{pmatrix} u & v \\ -\overline{v} & -\overline{u} \end{pmatrix}$, where $u$ is pure imaginary. A basis of $\mathfrak{su}(1, 1)$ is thus

$$\frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = -i \xi_1 = M_1, \quad \frac{1}{2} \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} = -i \xi_2 = M_2, \quad \frac{1}{2} \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix} = \xi_3 = M_3.$$

The commutation relations are

$$[M_1, M_2] = -M_3, \quad [M_2, M_3] = M_1, \quad [M_3, M_1] = M_2.$$

4. (a) If $x = \sum_{k=1}^{3} x_k e_k$, then $\alpha(x) = \sum_{k=1}^{3} x_k M_k = \frac{1}{2} \left( x_1 x_2 - i x_3 \right)$, whose determinant is $\frac{1}{4}(-x_1^2 + x_2^2 + x_3^2) = -\frac{1}{4} Q(x)$.

(b) By definition, $K(X, Y) = \text{Tr}(\text{ad}_X \text{ad}_Y)$. We have, in the basis $(M_k)$,

$$\text{ad}_{M_1} = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & -1 & 0 \end{pmatrix}, \quad \text{ad}_{M_2} = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \text{ad}_{M_3} = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}.$$

Set $X = \alpha(x) = \sum_{k=1}^{3} x_k M_k$ and set $Y = \alpha(y) = \sum_{k=1}^{3} y_k M_k$. Then

$$\text{ad}_X = \begin{pmatrix} 0 & -x_3 & x_2 \\ x_3 & 0 & -x_1 \\ -x_2 & x_1 & 0 \end{pmatrix},$$

whence $\text{Tr}(\text{ad}_X \text{ad}_Y) = 2(x_1 y_1 + x_2 y_2 - x_3 y_3)$. Thus $K(\alpha(x), \alpha(x)) = 2Q(x)$.

5. The group $O(2, 1)$ is the group of transformations of $\mathbb{R}^3$ preserving the quadratic form $Q$ of signature $(2,1)$, and therefore not positive definite. In fact, if $X$ is the column vector of components $x_1, x_2, x_3$, then

$$Q(x) = ^t X J_{21} X,$$

and if $A \in \text{GL}(3, \mathbb{R})$,

$$Q(Ax) = ^t X ^t A J_{21} A X,$$

then $Q(Ax) = Q(x)$ for every $x$ is equivalent to $^t A J_{21} A = J_{21}$. Now, because $(J_{21})^2 = I$, the condition $^t A \in O(2, 1)$ is equivalent to $A \in O(2, 1)$. In fact, $^t A J_{21} A = J_{21}$ implies $A J_{21} ^t A J_{21} A = A$, whence $A J_{21} ^t A = J_{21}$.

6. Using the same argument as in Question 3, we see that if $M \in \mathfrak{gl}(3, \mathbb{R})$, the condition $\exp(sM) J_{21} \exp(s \, ^t \!M) = J_{21}$, for every $s \in \mathbb{R}$, is equivalent to the condition $M J_{21} + J_{21} \, ^t \!M = 0$. The matrices $M$ of $\mathfrak{gl}(3, \mathbb{R})$ satisfying the condition $M J_{21} + J_{21} \, ^t \!M = 0$ are of the form $\begin{pmatrix} 0 & u & v \\ -u & 0 & w \\ -v & -w & 0 \end{pmatrix}$, where $u, v, w \in \mathbb{R}$. Thus $\text{Tr}M = 0$. The Lie algebra of $\text{SO}(2, 1)$ is thus

$$\mathfrak{so}(2, 1) = \{M \in \mathfrak{sl}(3, \mathbb{R}) \mid M J_{21} + J_{21} \, ^t \!M = 0\}.$$
The matrices
\[
\zeta_1 = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & -1 & 0 \end{pmatrix}, \quad \zeta_2 = \begin{pmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ 1 & 0 & 0 \end{pmatrix}, \quad \zeta_3 = \begin{pmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix},
\]
form a basis of \(\mathfrak{so}(2, 1)\).

The commutation relations are
\[
[\zeta_1, \zeta_2] = -\zeta_3, \quad [\zeta_2, \zeta_3] = \zeta_1, \quad [\zeta_3, \zeta_1] = \zeta_2.
\]

It follows from the remark above on the vanishing of the trace that the Lie algebra of \(O(2, 1)\) is equal to \(\mathfrak{so}(2, 1)\).

7. The linear mapping of \(\mathfrak{su}(1, 1)\) on \(\mathfrak{so}(2, 1)\) defined by \(M_k \mapsto \zeta_k\), for \(k = 1, 2, 3\), is an isomorphism of Lie algebras, since in these bases the commutation relations are the same in the two Lie algebras.

On the other hand, one can deduce from Question 2 above that the Lie algebras of \(SU(1, 1)\), and \(\mathfrak{sl}(2, \mathbb{R})\) are isomorphic. Thus the Lie algebras \(\mathfrak{so}(2, 1), \mathfrak{su}(1, 1), \) and \(\mathfrak{sl}(2, \mathbb{R})\) are isomorphic.

Observe that because \(\text{Tr}((\text{ad}\zeta_k)^2) = -2\), the Killing form of \(\mathfrak{su}(2)\) is negative definite. The Lie algebras \(\mathfrak{su}(1, 1)\) and \(\mathfrak{su}(2)\) are not isomorphic, since their Killing forms do not have the same signature.

8. (a) By definition \(\alpha \circ \psi(g) = \text{Ad}_g \circ \alpha\), for every \(g \in SU(1, 1)\). The linear mapping \(\text{Ad}_g\) preserves the determinants, and hence \(\psi(g)\) preserves \(Q\), because 
\[
\det \alpha(x) = -\frac{1}{4} Q(x), \quad \text{for every } x \in \mathbb{R}^3.
\]
Thus \(\psi(g) \in O(2, 1)\).

(b) Because \(SU(1, 1)\) is connected, the image of \(\psi\) is contained in the connected component of the identity of \(O(2, 1)\), which is the component \(SO_0(2, 1)\) of its subgroup \(SO(2, 1)\).

It is clear that \(\psi\) is a Lie group morphism. The kernel of \(\psi\) is the subgroup of \(SU(1, 1)\),
\[
\{ g \in SU(1, 1) \mid \text{Ad}_g = \text{Id}_{\mathfrak{su}(1, 1)} \} = \{ g \in SU(1, 1) \mid \forall M \in \mathfrak{su}(1, 1), gM = Mg \}.
\]

A calculation shows that \(g = \begin{pmatrix} a & b \\ \bar{b} & \bar{a} \end{pmatrix}\) satisfies this condition if and only if \(b = 0, a = \bar{a}\), whence \(a = \pm 1\) and \(\text{Ker} \, \psi = \{ I, -I \}\).

(c) The differential of \(\psi\) is the morphism of Lie algebras that associates to \(X \in \mathfrak{su}(1, 1)\) the matrix of \(\text{ad}_X\) in the basis \((M_k)\). This morphism is the isomorphism from \(\mathfrak{su}(1, 1)\) onto \(\mathfrak{so}(2, 1)\) constructed in Question 7 above, because the matrix of \(\text{ad}_{M_k}\) is \(\zeta_k\), for \(k = 1, 2, 3\), as we have seen in the proof of Questions 4(b) and 6.

On the other hand, each element of \(SO_0(2, 1)\) is a product of exponentials. Thus to show that \(\psi\) is surjective, it suffices to show that for every \(M \in \mathfrak{so}(2, 1)\), there is an \(N \in \mathfrak{su}(1, 1)\) such that \(\psi(\exp N) = \exp M.\) Because \(\psi(\exp N) = \exp((D\psi)N)\), and because \(D\psi\) is an isomorphism, it suffices to take 
\(N = (D\psi)^{-1}(M)\).
The morphism $\psi$ is a double cover of $SO_0(2,1)$. But $SU(1,1)$ is not simply connected. The universal cover of $SO_0(2,1)$ is an example of a Lie group that is not a linear Lie group.

We can define the analogue of Euler angles for $SU(1,1)$ and express the Haar integral in this parametrization. Since the Lie group $SU(1,1)$ is not compact, it has infinite-dimensional irreducible unitary representations. One can realize the representations of $SU(1,1)$ in spaces of homogeneous functions of a complex variable, study the special functions associated to the matrix coefficients of these representations, etc. See Vilenkin (1968) or Vilenkin–Klimyk (1991).

In physics, the noncompact Lie group $SO_0(3,2)$ is called the anti–de Sitter group, while $SO_0(4,1)$ is called the de Sitter group. The importance of the anti–de Sitter group is due to the fact that the Poincaré group can be obtained from it by contraction. The group $O(3,2)$ is the symmetry group of a one-sheeted hyperboloid in $\mathbb{R}^5$, called the anti–de Sitter space-time, $AdS_5$.

6 Irreducible Representations of $SU(2) \times SU(2)$

Let $\mathbb{H}$ be the associative algebra of quaternions, a real vector space of dimension 4 with basis $(1, i, j, k)$ and multiplication defined by

$$i^2 = j^2 = k^2 = -1, \quad ij = -ji = k, \quad jk = -kj = i, \quad ki = -ik = j.$$

For $q = \alpha_01 + \alpha_1i + \alpha_2j + \alpha_3k$, we set $\bar{q} = \alpha_01 - \alpha_1i - \alpha_2j - \alpha_3k$ and $\|q\|^2 = qq$. It is known that $\|q\|^2 = \sum_{p=0}^{3}(\alpha_p)^2$ and that for all $q, q' \in \mathbb{H}$,

$$\|qq'\| = \|q\| \|q'\|.$$

Denote by $S$ the group of unit quaternions

$$S = \{q \in \mathbb{H} \mid \|q\| = 1\}.$$
Consider the real vector space $\mathcal{H}$ generated by the matrices

\[
I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \mathcal{I} = \begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}, \quad \mathcal{J} = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}, \quad \mathcal{K} = \begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}.
\]

Observe that $SU(2)$ and $su(2)$ are contained in $\mathcal{H}$.

**Part I**

1. We write $M \mapsto q_M$ for the isomorphism of real vector spaces from $\mathcal{H}$ onto $\mathbb{H}$ defined by $I \mapsto 1$, $\mathcal{I} \mapsto i$, $\mathcal{J} \mapsto j$, $\mathcal{K} \mapsto k$.

   (a) Show that the restriction to $SU(2)$ of this map is an isomorphism from the group $SU(2)$ onto the group $S$.

   (b) Show that for every $X \in su(2)$,

   \[
   \frac{d}{dt}(q_{\exp(tX)})|_{t=0} = qX.
   \]

2. Let $(A, B) \in SU(2) \times SU(2)$. We consider the map

   \[
   \sigma(A, B) : \mathbb{H} \to \mathbb{H}
   \]

   defined by

   \[
   \sigma(A, B)q = qAq^{-1}(qB), \quad \forall q \in \mathbb{H}.
   \]

   We identify $\mathbb{H}$ and $\mathbb{R}^4$ by means of the $\mathbb{R}$-linear map defined by $1 \mapsto e_0$, $i \mapsto e_1$, $j \mapsto e_2$, $k \mapsto e_3$, where $(e_0, e_1, e_2, e_3)$ is the canonical basis of $\mathbb{R}^4$.

   (a) Show that $\sigma(A, B)$ can be identified with an element of $O(4)$.

   (b) Show that $\sigma$ is a group morphism from $SU(2) \times SU(2)$ into $SO(4)$.

   (c) Find the kernel of the morphism $\sigma$.

3. (a) Find the differential $D\sigma : su(2) \oplus su(2) \to so(4)$ of $\sigma$.

   (b) Show that $D\sigma$ is an isomorphism of Lie algebras.

   (c) Show that the image of $\sigma$ is $SO(4)$.

**Part II**

Let $(E_1, \rho_1)$ and $(E_2, \rho_2)$ be finite-dimensional representations of compact Lie groups $G_1$ and $G_2$, respectively. We define a representation $\rho$ of $G_1 \times G_2$ in $E_1 \otimes E_2$ by

\[
\rho(g_1, g_2)(v_1 \otimes v_2) = \rho_1(g_1)v_1 \otimes \rho_2(g_2)v_2,
\]

for $g_1 \in G_1$, $g_2 \in G_2$, $v_1 \in E_1$, $v_2 \in E_2$. We denote this representation by $\rho = \rho_1 \times \rho_2$.

We state without proof that each irreducible representation of $G_1 \times G_2$ is of the form $(E_1 \otimes E_2, \rho_1 \times \rho_2)$, where $(E_i, \rho_i)$ is an irreducible representation of $G_i$, $i = 1, 2$.

4. Find the irreducible representations of $SU(2) \times SU(2)$ and those of $SO(4)$. 
5. Let $\mathfrak{g}_1$ (respectively, $\mathfrak{g}_2$) be the Lie algebra of $G_1$ (respectively, $G_2$). Let $R$ be the differential of $\rho = \rho_1 \times \rho_2$. Evaluate $R(X_1, X_2)(v_1 \otimes v_2)$, for $X_1 \in \mathfrak{g}_1$, $X_2 \in \mathfrak{g}_2$, $v_1 \in E_1$, $v_2 \in E_2$, by means of $D\rho_1$ and $D\rho_2$. Denote by $D\rho_1 \times D\rho_2$ such a representation of $\mathfrak{su}(2) \oplus \mathfrak{su}(2)$ or of its complexification $\mathfrak{sl}(2, \mathbb{C}) \oplus \mathfrak{sl}(2, \mathbb{C})$.

6. Let $j_1, j_2 \in \frac{1}{2}\mathbb{N}$. Consider, with the notation of Question 5, the representation $D^{(j_1, j_2)} = D^{j_1} \times D^{j_2}$ of $\mathfrak{sl}(2, \mathbb{C}) \oplus \mathfrak{sl}(2, \mathbb{C})$ on $V^{j_1} \otimes V^{j_2}$. Set

$$J_1 = -\frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad J_2 = -\frac{i}{2} \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \quad J_3 = -\frac{1}{2} \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$  

Let $|j, m\rangle$ be the usual basis of the space $V^j$. Choose a basis of $V^{j_1} \otimes V^{j_2}$ and write the matrices of $D^{(j_1, j_2)}(X, 0)$ and of $D^{(j_1, j_2)}(0, X)$ in this basis,

(a) for $X = J_1$, $J_2$, $J_3$, when $j_1 = j_2 = \frac{1}{2}$,
(b) for $X = J_3$, when $j_1 = 1$ and $j_2 = \frac{1}{2}$,
(c) for $X = J_3$, when $j_1 = \frac{1}{2}$ and $j_2 = 1$.

7. Are the representations $D^{(j_1, j_2)}$ and $D^{(j_2, j_1)}$ equivalent? Why?

8. For $X \in \mathfrak{sl}(2, \mathbb{C})$, set $D_1^{(j_1, j_2)}(X^2) = D^{(j_1, j_2)}(X, 0) \circ D^{(j_1, j_2)}(X, 0)$ and $D_2^{(j_1, j_2)}(X^2) = D^{(j_1, j_2)}(0, X) \circ D^{(j_1, j_2)}(0, X)$. Set $C_i^{(j_1, j_2)} = \sum_{\ell=1}^3 D_i^{(j_1, j_2)}(J_\ell^2)$, $i = 1, 2$. Evaluate the operators $C_1^{(j_1, j_2)}$ and $C_2^{(j_1, j_2)}$.

9. We continue to use the notation of the preceding questions. We want to evaluate the multiplicity of the negative-energy bound states of a hydrogen atom. Let $e, m,$ and $\hbar$ be constants. We define the Rydberg constant

$$R_H = \frac{me^4}{2\hbar^2}.$$  

Let $R_\ell$ and $l_\ell$, $\ell = 1, 2, 3$, be elements of $\mathfrak{sl}(2, \mathbb{C})$. We set $R^2 = \sum_{\ell=1}^3 D_1^{(jj)}(R_\ell^2)$ and $l^2 = \sum_{\ell=1}^3 D_2^{(jj)}(l_\ell^2)$). Assume that

$$R^2 = e^4 + 2E\frac{l^2 + \hbar^2}{m},$$  

and that

$$-\frac{m}{2E}R^2 + l^2 = 2\hbar^2(C_1^{(jj)} + C_2^{(jj)}).$$  

Find the value of the energy $E$ as a function of the constant $R_H$ and the integer $n = 2j + 1$.

**Solutions**

**Part I**

1. (a) The map $M \mapsto q_M$ respects multiplication, since

$$I^2 = J^2 = K^2 = -I, \quad IJ = -JK = K,$$

$$JK = -KJ = I, \quad IK = -IK = J.$$
The restriction of this map is thus a group morphism. The image of SU(2) is $\mathbb{S}$, since if $A \in SU(2)$, $A = \alpha_0 I + \alpha_1 I + \alpha_2 J + \alpha_3 K$ with $\sum_{p=0}^{3}(\alpha_p)^2 = 1$; hence $q_A \in \mathbb{S}$, and conversely, each quaternion of norm 1 is the image of a matrix $A$ belonging to SU(2). Thus $A \in SU(2) \mapsto q_A \in \mathbb{S}$ is a group isomorphism.

(b) The vector space $\mathcal{H}$ is in fact a subalgebra of the associative algebra of complex $2 \times 2$ matrices (with matrix multiplication). If $X \in \mathfrak{su}(2)$, then $X^{k/k!} \in \mathcal{H}$ for each $k \in \mathbb{N}$, and one has, in $\mathbb{H}$,

\[ q_{\exp(tX)} = qI + tX + O(t^2) = 1 + tqX + O(t^2). \]

Hence $\frac{d}{dt}q_{\exp(tX)} \bigg|_{t=0} = qX$.

One can also use the equation $\exp(tX) = \cos t I + \sin t X$, which holds for $X \in \mathfrak{su}(2)$ of determinant 1, whence for every $X \in \mathfrak{su}(2)$,

\[ \exp(tX) = \cos(t\|X\|)I + \sin(t\|X\|)X / \|X\|, \]

whence $q_{\exp(tXY)} = \cos(t\|X\|)1 + 1 / \|X\| \sin(t\|X\|)qX$, and therefore $\frac{d}{dt}q_{\exp(tX)} \bigg|_{t=0} = qX$.

2. (a) In the identification of $\mathbb{H}$ with $\mathbb{R}^4$, the quaternion norm can be identified with the Euclidean norm. The map $\sigma(A, B)$ preserves the quaternion norm because

\[ \|q_Aq_B^{-1}\| = \|q_A\|\|q_B\| = \|(q_B)^{-1}\| = 1, \text{ for } A, B \in SU(2). \]

Thus $\sigma$ can be identified with an element of $O(4)$.

(b) Let $(A, B)$ and $(A', B')$ be elements of $SU(2) \times SU(2)$. Then

\[ \sigma(A, B) \circ \sigma(A', B') q = \sigma(A, B)(q_{A'}q(q_{B'})^{-1}) = q_Aq_{A'}q(q_{B'})^{-1}(q_B)^{-1}. \]

Now $A \mapsto q_A$ is a group morphism, and hence

\[ q_Aq_{A'} = q_{AA'} \quad \text{and} \quad (q_{B'})^{-1}(q_B)^{-1} = (q_Bq_{B'})^{-1} = (BB')^{-1}. \]

Hence

\[ \sigma(A, B) \circ \sigma(A', B') = \sigma(AA', BB'). \]

The image of $SU(2) \times SU(2)$ is contained in $SO(4)$ because $SU(2) \times SU(2)$ is connected.

(c) The kernel of $\sigma$ is the set of ordered pairs $(A, B)$ such that for every $q \in \mathbb{H}$, $q_Aq = qB$. Taking $q = 1$, we see that $q_A = q_B$. We set

\[ q_A = \alpha_0 I + \alpha_1 I + \alpha_2 J + \alpha_3 K. \]
The condition \( q_A i = iq_A \) implies
\[
\alpha_0 i - \alpha_1 - \alpha_2 k + \alpha_3 j = \alpha_0 i - \alpha_1 + \alpha_2 k - \alpha_3 j,
\]
whence
\[
\alpha_2 = \alpha_3 = 0.
\]
The condition \( q_A j = jq_B \) implies \( \alpha_1 = 0 \). One thus obtains \( q_A = q_B = \alpha_0 1 \).

Because \( \|q_A\| = 1 \), the solutions are \( q_A = q_B = \alpha_0 1 \).

The kernel of \( \sigma \) is thus the set \( \{(I, I), (-I, -I)\} \subset SU(2) \times SU(2) \).

3. (a) We have
\[
(D\sigma)(X, Y)q = \frac{d}{dt}\sigma(\exp(tX), \exp(tY))q\big|_{t=0} = \frac{d}{dt}(q_{\exp(tX)}q q_{\exp(-tY)})\big|_{t=0} = qx q - qy,
\]
by the equation \( \frac{d}{dt}q_{\exp(tX)}\big|_{t=0} = qx \).

(b) We know that \( D\sigma : su(2) \oplus su(2) \to so(4) \) and that \( D\sigma \) is a morphism of Lie algebras.

The kernel of \( D\sigma \) is the set of pairs \( (X, Y) \in su(2) \oplus su(2) \) such that \( qx q = qy \), for every \( q \in H \). This implies \( qx = qy = \alpha_0 1 \). Because \( X \) and \( Y \) belong to \( su(2) \), \( qx \) and \( qy \) are zero. Hence \( \text{Ker} D\sigma = (0, 0) \). Because \( su(2) \oplus su(2) \) and \( so(4) \) have the same dimension, 6, this injective morphism is an isomorphism.

(c) Every element of \( SO(4) \) can be written \( \exp Z_1 \cdots \exp Z_k \), where \( Z_\ell \in so(4) \). Because \( D\sigma \) is bijective, \( Z_\ell = D\sigma(X_\ell, Y_\ell) \) for some ordered pair \( (X_\ell, Y_\ell) \in su(2) \).

So \( \exp Z_\ell = \exp D\sigma(X_\ell, Y_\ell) = \sigma(\exp X_\ell, \exp Y_\ell) \); thus \( \exp Z_\ell \in \text{Im} \sigma \). We deduce that \( \exp Z_1 \cdots \exp Z_k \in \text{Im} \sigma \), and thus \( \text{Im} \sigma = SO(4) \).

Part II

4. The irreducible representations of \( SU(2) \times SU(2) \) are \( D^{j_1} \times D^{j_2} \), \((j_1, j_2) \in \frac{1}{2}\mathbb{N} \times \frac{1}{2}\mathbb{N} \). We set
\[
D^{(j_1, j_2)} = D^{j_1} \times D^{j_2}.
\]
The irreducible representations of \( SO(4) \) are the \( D^{(j_1, j_2)} \) that can be factored through the projection \( \sigma \) of \( SU(2) \times SU(2) \) onto \( SO(4) \), that is, that satisfy
\[
D^{(j_1, j_2)}(-I, -I) = \text{Id}_{V_{j_1} \otimes V_{j_2}}.
\]
Now,
\[
D^{(j_1, j_2)}(-I, -I)(v_1 \otimes v_2) = D^{j_1}(-I)v_1 \otimes D^{j_2}(-I)v_2 = (-1)^{j_1 + j_2} v_1 \otimes v_2.
\]
Therefore the irreducible representations of \( SO(4) \) are \( D^{(j_1, j_2)} \), \((j_1, j_2) \in \frac{1}{2}\mathbb{N} \times \frac{1}{2}\mathbb{N} \), such that \( j_1 + j_2 \in \mathbb{N} \).
The irreducible representations of SU(2) × SU(2) and their dimensions are thus

\begin{align*}
D^{(00)} & \quad D^{(0\frac{1}{2})} & \quad D^{(01)} & \quad D^{(0\frac{3}{2})} & \quad D^{(02)} & \quad \ldots & \quad D^{(0j_2)} & \quad \ldots \\
1 & \quad 2 & \quad 3 & \quad 4 & \quad 5 & \quad 2j_2 + 1 \\
D^{(\frac{1}{2}0)} & \quad D^{(\frac{1}{2}\frac{1}{2})} & \quad D^{(\frac{1}{2}1)} & \quad D^{(\frac{1}{2}\frac{3}{2})} & \quad D^{(\frac{1}{2}2)} & \quad \ldots & \quad D^{(\frac{1}{2}j_2)} & \quad \ldots \\
2 & \quad 4 & \quad 6 & \quad 8 & \quad 10 & \quad 2(2j_2 + 1) & \quad \ldots \\
D^{(10)} & \quad D^{(1\frac{1}{2})} & \quad D^{(11)} & \quad D^{(1\frac{3}{2})} & \quad D^{(12)} & \quad \ldots & \quad D^{(1j_2)} & \quad \ldots \\
3 & \quad 6 & \quad 9 & \quad 12 & \quad 15 & \quad 3(2j_2 + 1) & \quad \ldots \\
\vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \ldots \\
D^{(j_10)} & \quad D^{(j_1\frac{1}{2})} & \quad D^{(j_11)} & \quad D^{(j_1\frac{3}{2})} & \quad D^{(j_12)} & \quad \ldots & \quad D^{(j_1j_2)} & \quad \ldots \\
2j_1 + 1 & \quad 2(2j_1 + 1) & \quad 3(2j_1 + 1) & \quad 4(2j_1 + 1) & \quad 5(2j_1 + 1) & \quad (2j_1 + 1)(2j_2 + 1) & \quad \ldots \\
\vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \ldots \\
\end{align*}

The irreducible representations of SO(4) are

\begin{align*}
D^{(00)} & \quad D^{(01)} & \quad D^{(02)} & \quad \ldots & \quad D^{(0j_2)} & \quad j_2 \text{ integer} \\
D^{(\frac{1}{2}\frac{1}{2})} & \quad D^{(\frac{1}{2}\frac{3}{2})} & \quad \ldots & \quad D^{(\frac{1}{2}j_2)} & \quad j_2 \text{ half-integer} \\
D^{(10)} & \quad D^{(1\frac{1}{2})} & \quad D^{(11)} & \quad D^{(1\frac{3}{2})} & \quad D^{(1j_2)} & \quad j_2 \text{ integer} \\
\vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \ldots \\
\ldots & \quad \ldots & \quad \ldots & \quad \ldots & \quad \ldots & \quad \ldots \\
\end{align*}

5. By definition, we have

\[
D(\rho_1 \times \rho_2)(X_1, X_2)(v_1 \otimes v_2) = \frac{d}{dt} \rho_1(\exp(tX_1))v_1 \otimes \rho_2(\exp(tX_2))v_2 |_{t=0} = D\rho_1(X_1)v_1 \otimes v_2 + v_1 \otimes D\rho_2(X_2)v_2.
\]

6. In \(V^j\), we use the basis \((|j, -j\rangle, |j, -j - 1\rangle, \ldots, |j, j - 1\rangle, |j, j\rangle\) in this order. The matrix of \(D^j(J_3)\) in this basis is

\[
\frac{-j}{\sqrt{2}j} \quad \frac{0}{\sqrt{2j}} \quad \frac{0}{\sqrt{2(2j-1)}} \\
\frac{0}{\sqrt{2}j} \quad \frac{-j+1}{\sqrt{2(2j-1)}} \quad \frac{0}{\sqrt{2(2j-1)}} \\
\frac{0}{\sqrt{2j}} \quad \frac{0}{\sqrt{2(2j-1)}} \quad \frac{j}{\sqrt{2(2j-1)}}
\]

On the other hand, \(J_\pm = J_1 \pm iJ_2\), whence \(J_1 = \frac{1}{2}(J_+ + J_-)\) and \(J_2 = -\frac{i}{2}(J_+ - J_-)\), whence

\[
D^j(J_1) = \frac{1}{2} \begin{pmatrix}
0 & \sqrt{2j} & 0 \\
\sqrt{2j} & 0 & \sqrt{2(2j-1)} \\
0 & \sqrt{2(2j-1)} & 0
\end{pmatrix}.
\]

On the other hand, \(J_\pm = J_1 \pm iJ_2\), whence \(J_1 = \frac{1}{2}(J_+ + J_-)\) and \(J_2 = -\frac{i}{2}(J_+ - J_-)\), whence

\[
D^j(J_1) = \frac{1}{2} \begin{pmatrix}
0 & \sqrt{2j} & 0 \\
\sqrt{2j} & 0 & \sqrt{2(2j-1)} \\
0 & \sqrt{2(2j-1)} & 0
\end{pmatrix}.
\]
In the basis \( |\frac{1}{2}, -\frac{1}{2}\>, |\frac{1}{2}, \frac{1}{2}\> \) of \( V^1 \),
\[
D^{\frac{1}{2}}(J_3) = \frac{1}{2} \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix} = J_3, \\
D^{\frac{1}{2}}(J_1) = \frac{1}{2} \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} = -J_1, \\
D^{\frac{1}{2}}(J_2) = \frac{1}{2} \begin{pmatrix} 0 & i \\ -i & 0 \end{pmatrix} = -J_2.
\]

In the basis \( |1, -1\>, |1, 0\>, |1, 1\> \) of \( V^1 \),
\[
D^1(J_3) = \begin{pmatrix} -1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 1 \end{pmatrix}, 
\]
and
\[
D^1(J_1) = \frac{1}{2} \begin{pmatrix} 0 & \sqrt{2} & 0 \\ \sqrt{2} & 0 & \sqrt{2} \\ 0 & \sqrt{2} & 0 \end{pmatrix}, \\
D^1(J_2) = \frac{1}{2} \begin{pmatrix} 0 & i\sqrt{2} & 0 \\ -i\sqrt{2} & 0 & i\sqrt{2} \\ 0 & -i\sqrt{2} & 0 \end{pmatrix}.
\]

By definition,
\[
D^{(j_1, j_2)}(X, 0) = D^{j_1}(X) \otimes \text{Id}_{V^{j_2}}, \\
D^{(j_1, j_2)}(0, X) = \text{Id}_{V^{j_1}} \otimes D^{j_2}(X).
\]

We set, for fixed \( j_1 \) and \( j_2 \), \( |j_1, m_1\> \otimes |j_2, m_2\> = |m_1; m_2\> \), and we use the basis
\[
(|-j_1; -j_2\>, |-(j_1; -j_2 + 1\>, \ldots, |-(j_1; j_2\>, |-j_1 + 1; -j_2\>, \ldots,
|-(j_1 + 1; j_2\>, \ldots, |j_1 + j_2\>).
\]

(a) Let \( j_1 = j_2 = \frac{1}{2} \). Then
\[
D^{(\frac{1}{2}, \frac{1}{2})}(J_3, 0) = \frac{1}{2} \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & -1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \\
D^{(\frac{1}{2}, \frac{1}{2})}(0, J_3) = \frac{1}{2} \begin{pmatrix} -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & -1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \\
D^{(\frac{1}{2}, \frac{1}{2})}(J_1, 0) = \frac{1}{2} \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}, \\
D^{(\frac{1}{2}, \frac{1}{2})}(0, J_1) = \frac{1}{2} \begin{pmatrix} 0 & 1 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 1 & 0 \end{pmatrix}.
\]
and

\[
D(\frac{1}{2}, \frac{1}{2})(J_2, 0) = \frac{1}{2} \begin{pmatrix}
0 & 0 & i & 0 \\
0 & 0 & 0 & i \\
-i & 0 & 0 & 0 \\
0 & -i & 0 & 0 \\
\end{pmatrix},
\quad D(\frac{1}{2}, \frac{1}{2})(0, J_2) = \frac{1}{2} \begin{pmatrix}
0 & i & 0 & 0 \\
-i & 0 & 0 & 0 \\
0 & 0 & 0 & i \\
0 & 0 & -i & 0 \\
\end{pmatrix}.
\]

(b) Set \( j_1 = 1 \) and \( j_2 = \frac{1}{2} \). Then

\[
D(1, \frac{1}{2})(J_3, 0) = \begin{pmatrix}
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
\end{pmatrix},
\]

\[
D(\frac{1}{2}, 0)(J_3) = \frac{1}{2} \begin{pmatrix}
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & -1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
\end{pmatrix}.
\]

(c) Let \( j_1 = \frac{1}{2} \) and \( j_2 = 1 \). Then

\[
D(\frac{1}{2}, 1)(J_3, 0) = \frac{1}{2} \begin{pmatrix}
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & -1 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
\end{pmatrix},
\]

\[
D(1, \frac{1}{2})(0, J_3) = \begin{pmatrix}
-1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 \\
\end{pmatrix}.
\]

7. If \( j_1 > j_2 \), then \( j_1 \) is an eigenvalue of \( D(j_1 j_2)(J_3, 0) \) and not of \( D(j_2 j_1)(J_3, 0) \). Thus the representation \( D(j_1 j_2) \) is equivalent to \( D(j_2 j_1) \) if and only if \( j_1 = j_2 \).
8. We have
\[\sum_{\ell=1}^{3} D^{(j_1j_2)}_{\ell}(J_2^{\ell}) (v_1 \otimes v_2) = \sum_{\ell=1}^{3} D^{j_1}(J_2^{\ell}) v_1 \otimes v_2 = j_1(j_1+1)v_1 \otimes v_2\]
for \(v_1 \in V^{j_1}\) and \(v_2 \in V^{j_2}\), and a similar result for \(\sum_{\ell=1}^{3} D^{(j_1j_2)}_{2}(J_2^{\ell})\). Hence
\[C_i^{(j_1j_2)} = j_i(j_i+1)\text{Id}_{V^{j_1} \otimes V^{j_2}}, \quad i = 1, 2.\]

9. From \(R^2 = e^4 + 2E l^2 + \hbar^2/m\), we find that
\[-\frac{m}{2E} R^2 + l^2 + \hbar^2 = -\frac{me^4}{2E},\]
whence, by replacement from \(-\frac{m}{2E} R^2 + l^2 = 2\hbar^2(C_1^{(jj)} + C_2^{(jj)})\),
\[\hbar^2(2(C_1^{(jj)} + C_2^{(jj)}) + 1) = -\frac{me^4}{2E}.\]
Because \(C_1^{(jj)} = C_2^{(jj)} = j(j + 1)\), and since we set \(\frac{me^4}{2\hbar^2} = R_H\), we obtain
\[E = -\frac{R_H}{(2j + 1)^2},\]
or
\[E = -\frac{R_H}{n^2}.\]

The degeneracy of the energy level \(E = -R_H/n^2\) of the hydrogen atom is the dimension \((2j + 1)^2 = n^2\) of the corresponding eigenspace of the Hamiltonian operator that is the support of the irreducible representation \(D^{(jj)}\) of \(\text{SO}(4)\). This degeneracy, which has been observed experimentally, can therefore be explained by the fact that the full symmetry group of the hydrogen atom is the group \(\text{SO}(4)\), a symmetry group larger than the obvious symmetry group \(\text{SO}(3)\). This is what is called the hidden symmetry of the hydrogen atom. See, for example, Singer (2005) or Gilmore (2008). The operator \((R_1, R_2, R_3)\) corresponds to the Lenz–Pauli vector \(\vec{R}\) in classical mechanics. The fact that it involves a representation with \(j_1 = j_2\) is a consequence of the fact that the Lenz–Pauli vector \(\vec{R}\) is orthogonal to the angular momentum \(\vec{\ell}\). In other words, the constant called the Rydberg constant is \(R'_H = R_H/h = R_H/2\pi\hbar\). The values of these constants are \(R_H = 13.61\) eV and \(R'_H = 3.29 \times 10^{-15}\) s\(^{-1}\). See also Sudbery (1986) and Blaizot–Toédano (1997).

7 Projection Operators

Part I

Let \(G = \mathfrak{S}_3\) be the symmetric group on three elements. We denote by \(e\) the identity, by \(c\) the cyclic permutation \(1 \ 2 \ 3\) and by \(t\) the transposition \(1 \ 2\ 3\). We denote by \(\rho_0\) the representation of \(\mathfrak{S}_3\) in \(\mathbb{C}^2\) such that
Projection Operators 161

\[ \rho_0(c) = \begin{pmatrix} j & 0 \\ 0 & j^2 \end{pmatrix}, \quad \rho_0(t) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \]

where \( j \) is the zero of \( x^2 + x + 1 \) with positive imaginary part.

Let \( E = \mathcal{F}(G) = \mathbb{C}[G] \), the vector space of functions on \( G \) taking values in \( \mathbb{C} \), with basis \(( \epsilon_g )_{g \in G} \). Let \(( E, R )\) be the regular representation of \( G \).

1. Write the decomposition of \( R \) as a direct sum of irreducible representations.

We propose finding a vector subspace of \( E \) invariant under \( R \) and such that the restriction of \( R \) to this subspace is equivalent to \( \rho_0 \).

We denote by \( \rho_{\alpha \beta} \) the matrix coefficients of \( \rho_0 \) \((1 \leq \alpha \leq 2, \ 1 \leq \beta \leq 2)\), and we set

\[ P_{\alpha \beta} = \frac{1}{3} \sum_{g \in G} \rho_{\beta \alpha}(g^{-1})R(g) \in \text{End}(E). \]

2. (a) Find the matrices \( \rho_0(e), \rho_0(c^2), \rho_0(tc), \rho_0(tc^2) \).

(b) Express \( P_{11}, P_{22}, P_{21}, \) and \( P_{12} \) explicitly as linear combinations of \( R(g), g \in G \).

(c) Calculate \( P_{11}(\epsilon_h) \), for every \( h \in G \). What is the dimension of the vector subspace \( P_{11}(E) \) of \( E \)? Is it invariant under \( R \)?

(d) Same questions as in (c) replacing \( P_{11} \) by \( P_{22} \).

3. Choose a basis \(( u_1, u'_1 )\) of \( P_{11}(E) \).

(a) Calculate \( P_{21}(u_1) \) and show that \( P_{21}(u_1) \in P_{22}(E) \).

(b) Let \( E_{0,1} \) be the vector subspace of \( E \) generated by \( u_1 \) and \( P_{21}(u_1) \). Show that \( E_{0,1} \) is invariant under \( R \) and that the restriction of \( R \) to \( E_{0,1} \) is equivalent to \( \rho_0 \).

(c) What can be said about \( R\big|_{E'_{0,1}} \), where \( E'_{0,1} \) is the vector subspace of \( E \) generated by \( u'_1 \) and \( P_{21}(u'_1) \)?

4. Show that \( P_{11} + P_{22} \) is the projection \( P_0 \) of \( E \) onto the isotypic component of type \( \rho_0 \) of \( E \), and that \( P_0(E) = E_{0,1} \oplus E'_{0,1} \).

Part II

Let \( G \) be a finite group, and let \( (E^{(i)}, \rho^{(i)}), \ i = 1, \ldots, N, \) be its inequivalent irreducible representations. We set \( \dim E^{(i)} = d_i \) and we denote by \( \rho^{(i)}_{\alpha \beta} \), for \( 1 \leq \alpha \leq d_i, \ 1 \leq \beta \leq d_i \), the matrix coefficients of the representation \( \rho^{(i)} \) in a basis \(( e_{\alpha} )\) of \( E^{(i)} \). We recall that for all integers \( \alpha, \beta, \lambda, \mu \) between 1 and \( d_i \),

\[
\sum_{g \in G} \rho^{(i)}_{\beta \alpha}(g^{-1})\rho^{(j)}_{\lambda \mu}(g) = \begin{cases} 0 & \text{if } i \neq j, \\ \frac{|G|}{d_i} \delta_{\alpha \lambda} \delta_{\beta \mu} & \text{if } i = j. \end{cases}
\]
Let \((E, \rho)\) be a representation of \(G\). We set \(E = \bigoplus_{i=1}^N V^{(i)}\), with \(V^{(i)} = m_i E^{(i)}\), where \(m_i\) is the multiplicity of \(E^{(i)}\) in \(E\). We fix the index \(i, 1 \leq i \leq N\), and for \(1 \leq \alpha \leq d_i, 1 \leq \beta \leq d_i\), we consider
\[
P^{(i)}_{\alpha \beta} = \frac{d_i}{|G|} \sum_{g \in G} \rho^{(i)}_{\beta \alpha}(g^{-1}) \rho(g) \in \text{End}(E).
\]

5. Compare \(\sum_{\alpha=1}^{d_i} P^{(i)}_{\alpha \alpha}\) to the projection \(P^{(i)}\) of \(E\) onto the isotypic component \(V^{(i)}\) of \(E\).

6. Set \(1 \leq i \leq N, 1 \leq j \leq N\). Show that \(P^{(i)}_{\alpha \beta}(V^{(j)}) = \{0\}\) if \(j \neq i\), and that
\[
P^{(i)}_{\alpha \beta}(e_\gamma) = \delta_{\beta \gamma} e_\alpha \quad \text{for } 1 \leq \gamma \leq d_i.
\]

7. (a) Let \(\alpha, \beta, \lambda, \mu\) be integers between 1 and \(d_i\). Show that \(P^{(i)}_{\alpha \beta} \circ P^{(j)}_{\lambda \mu} = 0\) if \(i \neq j\), and that
\[
P^{(i)}_{\alpha \beta} \circ P^{(i)}_{\lambda \mu} = \delta_{\beta \lambda} P^{(i)}_{\alpha \mu}.
\]

(b) Conclude that \(P^{(i)}_{\alpha \beta}\) vanishes on \(P^{(i)}_{\gamma \gamma}(E)\) if \(\gamma \neq \beta\), and that \(P^{(i)}_{\alpha \beta}\) defines an isomorphism of \(P^{(i)}_{\beta \beta}(E)\) onto \(P^{(i)}_{\alpha \alpha}(E)\).

8. Show that \(\rho(g) \circ P^{(i)}_{\alpha \beta} = \sum_{\gamma=1}^{d_i} \rho^{(i)}_{\gamma \alpha}(g) P^{(i)}_{\gamma \beta}\).

9. Let \(x \in P^{(i)}_{11}(E), x \neq 0\). For \(\beta = 1, \ldots, \) set \(d_i, x_\beta = P^{(i)}_{\beta 1}(x)\). Let \(E^{(i)}(x)\) be the vector subspace of \(E\) generated by \((x_1, \ldots, x_{d_i})\). Show that the restriction of \(\rho\) to \(E^{(i)}(x)\) is equivalent to \(\rho^{(i)}\).

10. Construct \(m_i\) vector subspaces of \(E\) whose direct sum is \(V^{(i)}\) and such that the restriction of \(\rho\) to each is equivalent to \(\rho^{(i)}\).

11. Define projection operators \(P^{(i)}_{\alpha \beta}\) in order to apply an analogous procedure to the decomposition of a representation of a compact group.

Solutions

Part I

1. The irreducible representations of \(G = \mathfrak{S}_3\) are the trivial representation \(1\) and the signature representation \(\epsilon\), both one-dimensional, and the two-dimensional representation \(\rho_0\). Hence
\[
R = 1 \oplus \epsilon \oplus 2 \rho_0.
\]

2. (a) By calculating matrix products, we obtain
\[
\rho_0(e) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad \rho_0(c) = \begin{pmatrix} j & 0 \\ 0 & j^2 \end{pmatrix}, \quad \rho_0(c^2) = \begin{pmatrix} j^2 & 0 \\ 0 & j \end{pmatrix},
\]
\[
\rho_0(t) = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \rho_0(tc) = \begin{pmatrix} 0 & j^2 \\ j & 0 \end{pmatrix}, \quad \rho_0(tc^2) = \begin{pmatrix} 0 & j \\ j^2 & 0 \end{pmatrix}.
\]
We shall make use of the equations $c^3 = e$, $t^2 = e$, $ct = tc^2$, $c^2t = tc$, and $ctc = t$.

(b) We note that $c^{-1} = c^2$, $(c^2)^{-1} = c$. By definition,

\[
P_{11} = \frac{1}{3}(R(e) + j^2R(c) + jR(c^2)), \quad P_{22} = \frac{1}{3}(R(e) + jR(c) + j^2R(c^2)).
\]

Because $t$, $tc$, and $tc^2$ are equal to their inverses, and since $e$, $c$, and $c^2$ are diagonal, we obtain

\[
P_{12} = \frac{1}{3} \sum_{g \in G} \rho_{21}(g^{-1})R(g) = \frac{1}{3}(R(t) + jR(tc) + j^2R(tc^2)),
\]

\[
P_{21} = \frac{1}{3} \sum_{g \in G} \rho_{12}(g^{-1})R(g) = \frac{1}{3}(R(t) + j^2R(tc) + jR(tc^2)).
\]

(c) We know that $R(g)e_h = e_{gh}$, for $g, h \in G$. Thus

\[
P_{11}(e_h) = \frac{1}{3}(e_h + j^2e_{ch} + je_{c^2h}).
\]

Hence

\[
P_{11}(e_e) = \frac{1}{3}(e_e + j^2e_c + je_{c^2}),
\]

\[
P_{11}(e_t) = \frac{1}{3}(e_t + j^2e_{ct} + je_{c^2t}) = \frac{1}{3}(e_t + je_{tc} + j^2e_{tc^2}).
\]

We set

\[
P_{11}(e_e) = u_1, \quad P_{11}(e_t) = u'_1,
\]

which are linearly independent. Then,

\[
P_{11}(e_c) = ju_1, \quad P_{11}(e_{c^2}) = j^2u_1,
\]

\[
P_{11}(e_{tc}) = j^2u'_1, \quad P_{11}(e_{tc^2}) = ju'_1.
\]

Thus $P_{11}(E)$ is two-dimensional.

We have $R(t)u_1 = \frac{1}{3}(e_t + j^2e_{tc} + je_{tc^2})$, which does not lie in $P_{11}(E)$. Thus $P_{11}(E)$ is not invariant under $R$.

(d) By (b) and the equation $R(g)e_h = e_{gh}$, we obtain

\[
P_{22}(e_h) = \frac{1}{3}(e_h + je_{ch} + j^2e_{c^2h}).
\]

Hence

\[
P_{22}(e_e) = \frac{1}{3}(e_e + je_c + j^2e_{c^2}),
\]

\[
P_{22}(e_t) = \frac{1}{3}(e_t + je_{ct} + j^2e_{c^2t}) = \frac{1}{3}(e_t + j^2e_{tc} + je_{tc^2}).
\]
We set 
\[ P_{22}(\epsilon_t) = v_1, \quad P_{22}(\epsilon_c) = v'_1, \]
which are linearly independent. We have 
\[ P_{22}(\epsilon_c) = j^2 v'_1, \quad P_{22}(\epsilon_c^2) = j v'_1, \]
\[ P_{22}(\epsilon_{tc}) = jv_1, \quad P_{22}(\epsilon_{tc^2}) = j^2 v_1. \]
Thus \( P_{22}(E) \) is two-dimensional.

We have \( R(t)v_1 = \frac{1}{3}(\epsilon_c + j^2 \epsilon_c + j \epsilon_{c^2}) \), which does not lie in \( P_{22}(E) \). Thus \( P_{22}(E) \) is not invariant under \( R \).

3. (a) We calculate 
\[ P_{21}(u_1) = \frac{1}{3}(R(t)u_1 + j^2 R(tc)u_1 + jR(tc^2)u_1). \]
We have 
\[ R(t)u_1 = \frac{1}{3}(\epsilon_t + j^2 \epsilon_{tc} + j \epsilon_{tc^2}) = v_1, \]
\[ R(tc)u_1 = \frac{1}{3}(\epsilon_{tc} + j^2 \epsilon_{tc^2} + j \epsilon_t) = jv_1, \]
\[ R(tc^2)u_1 = \frac{1}{3}(\epsilon_{tc^2} + j^2 \epsilon_t + j \epsilon_{tc}) = j^2 v_1. \]
Hence \( P_{21}(u_1) = v_1 \), which belongs to \( P_{22}(E) \). Furthermore, \( u_1 \) and \( v_1 \) are linearly independent.

(b) We have \( R(e)u_1 = \frac{1}{3}(\epsilon_c + j^2 \epsilon_{c^2} + j \epsilon_e) = j u_1 \) and \( R(t)u_1 = v_1 \), and thus \( u_1 \) and \( P_{21}(u_1) \) generate a two-dimensional vector subspace \( E_{0,1} \) of \( E \), invariant under \( R \). We have \( R(e)v_1 = \frac{1}{3}(\epsilon_{e^2} + j \epsilon_{tc} + j^2 \epsilon_t) = j^2 v_1 \) and \( R(t)v_1 = \frac{1}{3}(\epsilon_e + j \epsilon_{c^2} + j^2 \epsilon_c) = u_1 \). Thus the matrices of \( R|_{E_{0,1}} \) in the basis \( (u_1, v_1) \) are 
\[ C = \begin{pmatrix} j & 0 \\ 0 & j^2 \end{pmatrix}, \quad T = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}. \]
Thus \( R|_{E_{0,1}} \) is equivalent to \( \rho_0 \).

(c) Similarly, \( R|_{E_{0,1}'} \) is equivalent to \( \rho_0 \).

4. By definition,
\[ P_{11} + P_{22} = \frac{1}{3} \sum_{g \in G} (\rho_{11}(g^{-1}) + \rho_{22}(g^{-1}))R(g) \]
\[ = \frac{1}{3} \sum_{g \in G} \overline{\chi_{\rho_0}(g)}R(g), \]
where \( \chi_{\rho_0} \) is the character of the representation \( \rho_0 \). We know that this endomorphism of \( E \) is the projection \( P_0 \) onto the isotypic component of type \( \rho_0 \), which here has multiplicity two. Because \( E_{0,1} \) and \( E_{0,1}' \) are of type \( \rho_0 \) and have trivial intersection \( \{0\} \), we have 
\[ P_0(E) = E_{0,1} \oplus E_{0,1}'. \]
Part II

5. We know that \( \sum_{\alpha=1}^{d_i} \rho_{\alpha \alpha}^{(i)}(g^{-1}) = \chi_{\rho^{(i)}}(g^{-1}) = \chi_{\bar{\rho}^{(i)}}(g) \). Thus, by the definitions,

\[
\sum_{\alpha=1}^{d_i} P_{\alpha \alpha}^{(i)} = P^{(i)}.
\]

6. Let \((\varphi_\lambda), \lambda = 1, \ldots, d_j,\) be a basis of \(E^{(j)}\). Since \(\rho(g)(\varphi_\mu) = \sum_{\lambda=1}^{d_j} \rho_{\lambda \mu}^{(j)}(g) \varphi_\lambda\), it follows from (1) that if \(i \neq j\), then

\[
P_{\alpha \beta}^{(i)}(\varphi_\mu) = \frac{d_i}{|G|} \sum_{\lambda=1}^{d_j} \left( \sum_{g \in G} \rho_{\beta \alpha}^{(i)}(g^{-1}) \rho_{\lambda \mu}^{(j)}(g) \right) \varphi_\lambda = 0.
\]

Because \(V^{(j)} = m_j E^{(j)}\), the operator \(P_{\alpha \beta}^{(i)}\) vanishes on \(V^{(j)}\).

On the other hand, using (1) for \(i = j\) yields

\[
P_{\alpha \beta}^{(i)}(e_\gamma) = \frac{d_i}{|G|} \sum_{\lambda=1}^{d_i} \left( \sum_{g \in G} \rho_{\beta \alpha}^{(i)}(g^{-1}) \rho_{\lambda \gamma}^{(i)}(g) \right) e_\lambda = \frac{d_i}{|G|} \sum_{\lambda=1}^{d_i} \delta_{\alpha \lambda} \delta_{\beta \gamma} e_\lambda = \delta_{\beta \gamma} e_\alpha.
\]

7. (a) We calculate

\[
P_{\alpha \beta}^{(i)} \circ P_{\lambda \mu}^{(j)} = \frac{d_i d_j}{|G|^2} \left( \sum_{g \in G} \rho_{\beta \alpha}^{(i)}(g^{-1}) \rho(g) \right) \circ \left( \sum_{h \in G} \rho_{\mu \lambda}^{(j)}(h^{-1}) \rho(h) \right)
\]

\[
= \frac{d_i d_j}{|G|^2} \sum_{g \in G} \sum_{h \in G} \rho_{\beta \alpha}^{(i)}(g^{-1}) \rho_{\mu \lambda}^{(j)}(h^{-1}) \rho(gh).
\]

Setting \(gh = k\), whence \(g^{-1} = hk^{-1}\), we obtain

\[
P_{\alpha \beta}^{(i)} \circ P_{\lambda \mu}^{(j)} = \frac{d_i d_j}{|G|^2} \sum_{k \in G} \left( \sum_{\gamma=1}^{d_i} \rho_{\beta \gamma}^{(i)}(h) \rho_{\gamma \alpha}^{(i)}(k^{-1}) \right) \rho(k).
\]

We use \(\rho_{\beta \alpha}^{(i)}(hk^{-1}) = \sum_{\gamma=1}^{d_i} \rho_{\beta \gamma}^{(i)}(h) \rho_{\gamma \alpha}^{(i)}(k^{-1})\) along with equation (1), and we obtain

\[
P_{\alpha \beta}^{(i)} \circ P_{\lambda \mu}^{(j)} = \frac{d_i d_j}{|G|^2} \sum_{k \in G} \sum_{\gamma=1}^{d_i} \left( \sum_{h \in G} \rho_{\beta \gamma}^{(i)}(h) \rho_{\mu \lambda}^{(j)}(h^{-1}) \right) \rho_{\gamma \alpha}^{(i)}(k^{-1}) \rho(k)
\]

\[
= \delta_{ij} \frac{d_i}{|G|} \sum_{k \in G} \sum_{\gamma=1}^{d_i} \delta_{\gamma \mu} \delta_{\beta \alpha} \rho_{\gamma \alpha}^{(i)}(k^{-1}) \rho(k)
\]

\[
= \delta_{ij} \delta_{\beta \alpha} \frac{d_i}{|G|} \sum_{k \in G} \rho_{\mu \alpha}^{(i)}(k^{-1}) \rho(k) = \delta_{ij} \delta_{\beta \alpha} P_{\alpha \mu}^{(i)},
\]

which proves the desired results.
(b) In particular, $P_{αα}^{(i)} ∘ P_{ββ}^{(j)} = 0$ if $i ≠ j$, and $P_{αα}^{(i)} ∘ P_{γγ}^{(i)} = 0$ if $γ ≠ β$. Furthermore,

$$P_{αα}^{(i)} ∘ P_{ββ}^{(i)} = 0 \text{ if } α ≠ β, \quad P_{αα}^{(i)} ∘ P_{αα}^{(i)} = P_{αα}^{(i)}.$$  

Therefore, the $P_{αα}^{(i)}$ are projection operators onto subspaces of $V^{(i)}$ such that their images $P_{αα}^{(i)}(E)$ and $P_{ββ}^{(i)}(E)$ have trivial intersection if $α ≠ β$.

We now show, by means of the result of part (a), that $P_{αβ}^{(i)}$ is an isomorphism of $P_{ββ}^{(i)}(E)$ onto $P_{αα}^{(i)}(E)$. We use

$$P_{αβ}^{(i)} ∘ P_{ββ}^{(i)} = P_{αβ}^{(i)} = P_{αα}^{(i)} ∘ P_{ββ}^{(i)}$$

to show that $P_{αβ}^{(i)}(P_{ββ}^{(i)}(E)) ⊂ P_{αα}^{(i)}(E)$. Let us show that the restriction of $P_{αβ}^{(i)}$ to $P_{ββ}^{(i)}(E)$ is bijective. It is injective, since if $u ∈ E$ satisfies $P_{αβ}^{(i)}P_{ββ}^{(i)}(u) = 0$, then $0 = P_{βα}^{(i)}P_{αβ}^{(i)}P_{ββ}^{(i)}(u) = P_{ββ}^{(i)}(u)$. It is also surjective onto $P_{αα}^{(i)}(E)$, because for every $u ∈ E$, and for every $β = 1, . . . , d_i$,

$$P_{αα}^{(i)}(u) = P_{αβ}^{(i)}P_{βα}^{(i)}(u) = P_{αβ}^{(i)}P_{ββ}^{(i)}P_{βα}^{(i)}(u),$$

and thus $P_{αα}^{(i)}(u)$ belongs to the image under $P_{αβ}^{(i)}$ of $P_{ββ}^{(i)}(E)$.

8. We calculate $ρ(g) ∘ P_{αβ}^{(i)} = \frac{d_i}{|G|} \sum_{h∈G} ρ_{βα}^{(i)}(h^{-1})ρ(g)ρ(h)$. We set $gh = k$, whence $h = g^{-1}k$ and $h^{-1} = k^{-1}g$. We obtain

$$ρ(g) ∘ P_{αβ}^{(i)} = \frac{d_i}{|G|} \sum_{k∈G} ρ_{βα}^{(i)}(k^{-1}g)ρ(k)$$

$$= \frac{d_i}{|G|} \sum_{k∈G} ρ_{γγ}^{(i)}(k^{-1})ρ_{γα}^{(i)}(g)ρ(k)$$

$$= \sum_{γ=1}^{d_i} ρ_{γα}^{(i)}(g)P_{γβ}^{(i)}.$$

9. We consider the family $(x_β = P_{β1}^{(i)}(x))$, $β = 1, . . . , d_i$, where $x ∈ P_{11}^{(i)}(E)$ and $x ≠ 0$. Let us show that $(x_1, . . . , x_β, . . . , x_{d_i})$ are linearly independent. We remark first that $x_1 = x$, since $(P_{11}^{(i)})^2 = P_{11}^{(i)}$. Assume that there are complex numbers $λ_1, . . . , λ_{d_i}$ such that $\sum_{β=1}^{d_i} λ_β P_{1α}^{(i)}P_{β1}^{(i)}(x) = 0$. Then for every $α = 1, . . . , d_i$,

$$\sum_{β=1}^{d_i} λ_β P_{1α}^{(i)}P_{β1}^{(i)}(x) = \sum_{β=1}^{d_i} λ_β δ_{αβ}P_{11}^{(i)}(x) = λ_α x.$$

Because $x ≠ 0$, we see that $λ_α = 0$ for each $α$. The vector space $E_1^{(i)}(x)$ generated by $(x_1, . . . , x_{d_i})$ is thus of dimension $d_i$. We also recall that $P_{β1}^{(i)}$ is an
isomorphism from $P_{11}^{(i)}(E)$ onto $P_{\beta\beta}^{(i)}(E)$ and that the $(P_{\beta\beta}^{(i)}(E))$, $\beta = 1, \ldots, d_i$, form a direct sum decomposition of $V^{(i)} = m_i E^{(i)}$.

By the equation proved in Question 8,

$$\rho(g)x_\beta = \rho(g)(P_{\beta\beta}^{(i)}(x)) = \sum_{\gamma=1}^{d_i} \rho^{(i)}_{\gamma\beta}(g) P^{(i)}_{\gamma\gamma}(x) = \sum_{\gamma=1}^{d_i} \rho^{(i)}_{\gamma\beta}(g)x_\gamma,$$

which shows that $\rho^{(i)}_{E^{(i)}_1(x)}$ is equivalent to $\rho^{(i)}$.

10. In order to obtain $m_i$ vector subspaces of $E$ whose direct sum is $V^{(i)}$ and on each of which the group acts by the representation $\rho^{(i)}$, it suffices to apply the procedure of Question 9 successively to the vectors of a basis of $P_{11}^{(i)}(E)$, as we did in Part I of this problem. In fact, we have seen that for fixed $x$ in $P_{11}^{(i)}(E)$, the corresponding vector subspace $E_1^{(i)}(x)$ is invariant under $G$. If $x$ and $y$ are linearly independent, $E_1^{(i)}(x) \cap E_1^{(i)}(y)$ reduces to $\{0\}$ by the irreducibility of the representation $\rho^{(i)}$.

We have already noted that the $(P^{(i)}_{\alpha\alpha}(E))$, $\alpha = 1, \ldots, d_i$, form a direct sum.

Since $V^{(i)} = P^{(i)}(E) = \left( \sum_{\alpha=1}^{d_i} P^{(i)}_{\alpha\alpha}(E) \right)$, we obtain

$$V^{(i)} = \bigoplus_{\alpha=1}^{d_i} P^{(i)}_{\alpha\alpha}(E).$$

Because the $P^{(i)}_{\alpha\alpha}(E)$, $\alpha = 1, \ldots, d_i$, are isomorphic, we have dim $P^{(i)}_{\alpha\alpha}(E) = m_i$.

Thus by choosing $m_i$ basis vectors $(x^1, \ldots, x^{m_i})$ in $P_{11}^{(i)}(E)$ and by subjecting them to the process of Question 9, we obtain $m_i$ vector subspaces $E_1^{(i)}(x^A)$, $A = 1, \ldots, m_i$, such that $\rho^{(i)}_{E_1^{(i)}(x^A)}$ is equivalent to $\rho^{(i)}$ for every $A$, and

$$V^{(i)} = \bigoplus_{A=1}^{m_i} E_1^{(i)}(x^A).$$

This is the desired decomposition.

Clearly, Part I of this problem consisted in the direct study of a particular case of this process, where $\rho^{(i)} = \rho_0$, one has chosen the basis $(u_1, u'_1)$ of $P_{11}^{(i)}(E) = P_{11}(E)$, and one has set $E_1^{(i)}(u^1) = E_0, E_1^{(i)}(u'_1) = E'_0$.

11. For a compact group, we use the Haar integral $\int_G f(g) \rho(g)dg$ to define

$$P^{(i)}_{\alpha\beta} = d_i \int_G \rho^{(i)}_{\beta\alpha}(g^{-1}) \rho(g)dg,$$

and we proceed as in the case of a finite group.

This method is useful for determining the Clebsch–Gordan coefficients, and has many applications in quantum mechanics. See for example the study of the distribution of isotopic-spin states for a collection of free particles in Barut–Raczka (1977, 1986), p. 183.
In that book, on p. 177, the authors write, “The technique of the projection operators is extremely useful, elegant and effective in the solution of various practical problems in representation theory and quantum physics.”

8 Symmetries of Fullerene Molecules

We propose to study certain properties of the icosahedron group, which is the symmetry group of rotations of “soccer-ball molecules,” $C_{60}$, also called fullerenes or buckyballs.

Part I: Character table of $S_5$

We give below, without proof, the list of conjugacy classes of the symmetric group $S_5$ on five elements and the number of elements of each class. We denote by

- $e$ the class of the identity, with one element,
- $a$ the class of the permutation $(12): (1,2,3,4,5) \mapsto (2,1,3,4,5)$, with 10 elements,
- $\alpha$ the class of $(123): (1,2,3,4,5) \mapsto (2,3,1,4,5)$, with 20 elements,
- $b$ the class of $(1234): (1,2,3,4,5) \mapsto (2,3,4,1,5)$, with 30 elements,
- $\gamma$ the class of $(12345): (1,2,3,4,5) \mapsto (2,3,4,5,1)$, with 24 elements,
- $\beta$ the class of $(12)(34): (1,2,3,4,5) \mapsto (2,1,4,3,5)$, with 15 elements,
- $c$ the class of $(12)(345): (1,2,3,4,5) \mapsto (2,1,4,5,3)$, with 20 elements.

1. The permutation representation of $S_5$ decomposes as the direct sum of the trivial representation $\rho_1$ and a four-dimensional representation $\rho_4$. Find their characters. Find the character of the signature representation $\rho_1'$ as well as the character of the representation $\rho_4'$ obtained as the tensor product of $\rho_4$ with $\rho_1'$. Verify that $\rho_4$ and $\rho_4'$ are irreducible.

2. Show that for each finite-dimensional representation $(V, \rho)$ of a finite group $G$ of character $\chi_\rho$, the character of the representation $\wedge^2 \rho$ satisfies

$$\chi_{\wedge^2 \rho}(g) = \frac{1}{2}((\chi_\rho(g))^2 - \chi_\rho(g^2));$$

and that $\chi_{S^2 \rho} = (\chi_\rho)^2 - \chi_{\wedge^2 \rho}$. (Here $\wedge$ denotes the exterior product and $S$ the symmetric product.)

3. Calculate the characters of the representations $\wedge^2(\rho_4)$ and $S^2(\rho_4)$. [Hint: Use the equations $\alpha^2 = \alpha$, $b^2 = b$, $\gamma^2 = \gamma$, $c^2 = \alpha$.] Show that $\wedge^2(\rho_4)$ is irreducible. Show that $S^2(\rho_4)$ is a direct sum of three irreducible representations, and then show that $S^2(\rho_4) = \rho_1 \oplus \rho_4 \oplus \rho_5$, where $\rho_5$ is a five-dimensional irreducible representation.

4. Give the character table of $S_5$. 

Part II: Character table of $\mathfrak{A}_5$

Here is the list of conjugacy classes of the alternating group $\mathfrak{A}_5$ with the number of elements of each class:

- $e$ the class of the identity, with one element,
- $\alpha$ the class of $(123)$, with 20 elements,
- $\beta$ the class of $(12)(34)$, with 15 elements,
- $\gamma$ the class of $(12345)$, with 12 elements,
- $\gamma^2$ the class of $(23451)$: $(1,2,3,4,5) \mapsto (3,4,5,1,2)$, with 12 elements.

5. Show that the representations $\rho_1, \rho_4$, and $\rho_5$ stay irreducible when restricted to $\mathfrak{A}_5$. We denote these also by $\rho_1, \rho_4, \rho_5$.

Show that the restriction to $\mathfrak{A}_5$ of $\wedge^2(\rho_4)$ is the direct sum of two inequivalent irreducible representations $\rho_3$ and $\rho'_3$, and that each of them is three-dimensional.

6. Let $\tau = \frac{1 + \sqrt{5}}{2}$ be the golden mean. Show that the values of the characters of the representations $\rho_3$ and $\rho'_3$ of $\mathfrak{A}_5$ on the classes $(e, \alpha, \beta, \gamma, \gamma^2)$ are $(3,0,-1,\tau,1-\tau)$ and $(3,0,-1,1-\tau,\tau)$.

7. Find the character table of $\mathfrak{A}_5$.

Part III: Some representations of the icosahedron group

It is known that the group $\mathfrak{A}_5$ can be identified with the subgroup $\mathcal{I}$ of the group of rotations of $\mathbb{R}^3$ leaving a regular icosahedron invariant. In this identification, the elements of the conjugacy classes $(e, \alpha, \beta, \gamma, \gamma^2)$ of $\mathfrak{A}_5$ become rotations through angles $(0, 2\pi/3, \pi, 2\pi/5, 4\pi/5)$, respectively. We recall that $2\cos \frac{\pi}{5} = \frac{1 + \sqrt{5}}{2} = \tau$.

8. Denote by $\varphi$ the covering morphism of SU(2) onto SO(3). What is the image under $\varphi$ of the element $g_\alpha = \left( \begin{array}{cc} e^{i\alpha} & 0 \\ 0 & e^{-i\alpha} \end{array} \right)$?

For $j \in \mathbb{N}$, we denote by $\mathcal{D}^j$ the irreducible representation of dimension $2j+1$ of SO(3) obtained from the representation $\mathcal{D}^j$ of SU(2) by passing to the quotient. Show that the value of the character $\chi_{\mathcal{D}^j}$ of $\mathcal{D}^j$ on a rotation through an angle $\theta \in [0, \pi]$ is

$$\chi_{\mathcal{D}^j}(\theta) = \sum_{m=-j}^{j} e^{im\theta}.$$ 

For each $j \in \mathbb{N}$, we consider the restriction to the subgroup $\mathcal{I}$ of the representation $\mathcal{D}^j$. We denote it by $R^j$ and its character by $\chi^j$.

9. Calculate $\chi^j$ for $j \in \mathbb{N}$. Show that for each element $g \in \mathcal{I}, g \neq e$, of $\mathcal{I}$ and for every integer $\ell \in \mathbb{N}$,

$$\chi^{30\ell+j}(g) = \chi^j(g).$$

10. Show that the representations $R^0, R^1$, and $R^2$ of the group $\mathcal{I}$ are irreducible. Decompose the representation $R^3$ into a direct sum of irreducible representations, and then decompose the representations $R^{30\ell+3}$, for every integer $\ell \geq 1$. 
11. Decompose the representation $R^2 \otimes R^3$ of the group $I$ into a direct sum of irreducible representations.

**Epilogue: Representations of $G = \varphi^{-1}(I) \subset SU(2)$**

Similarly, we can study the representations of the double cover of the icosahedron group, the inverse image of the group $I$ under the morphism $\varphi$. It is a subgroup $G$ of $SU(2)$ with 120 elements. It has nine conjugacy classes, whose representatives are $g_\alpha$, with

$$\alpha = 0, \pi, \frac{\pi}{2}, \frac{\pi}{3}, \frac{4\pi}{3}, \frac{\pi}{5}, \frac{7\pi}{5}, \frac{6\pi}{5}, \frac{2\pi}{5}.$$ 

These classes have 1, 1, 30, 20, 20, 12, 12, 12, 12 elements respectively. Can you find the character table of $G$? Can you show that restricted to $G$, the representation $D_j$ of $SU(2)$ is irreducible for $0 \leq j \leq \frac{5}{2}$? Can you find the decomposition of the restrictions to $G$ of the representations $D_j$, $j \in \frac{1}{2} \mathbb{N}$, into a direct sum of irreducible representations?

**Solutions**

**Part I: Character table of $S_5$**

1. Let $\rho_1$ be the one-dimensional trivial representation. We know that $\chi_{\rho_1}(g) = 1$, for every $g$. In the permutation representation, $\chi(g)$ is the number of elements that are invariant under $g$. Because $\chi_{\rho_1} + \chi_{\rho_4} = \chi$, we obtain the following character table:

<table>

</tbody>
</table>

We calculate $(\chi_{\rho_1} | \chi_{\rho_4}) = (\chi_{\rho_4} | \chi_{\rho_4}) = \frac{1}{120} (16 + 40 + 20 + 24 + 20) = 1$, and thus $\rho_4$ and $\rho_4'$ are irreducible.

2. The representation $\rho$ is unitarizable, so for every $g \in G$, $\rho(g)$ is diagonalizable. Let $(e_i)$ be a basis of $V$ such that $\rho(g)e_i = \lambda_i(g)e_i$, where $\lambda_i(g) \in \mathbb{C}$. Then

$$(\rho(g) \otimes \rho(g))(e_i \otimes e_j - e_j \otimes e_i) = \lambda_i(g)\lambda_j(g)(e_i \otimes e_j - e_j \otimes e_i),$$
whence
\[
\chi^{\wedge^2 \rho}(g) = \sum_{i<j} \lambda_i(g)\lambda_j(g) = \frac{1}{2}\left(\left(\sum_i \lambda_i(g)\right)^2 - \sum_i (\lambda_i(g))^2\right)
\]
\[
= \frac{1}{2}\left((\chi_{\rho}(g))^2 - \chi_{\rho}(g^2)\right).
\]

Because $\rho \otimes \rho = \wedge^2 \rho \oplus S^2 \rho$, we have $\chi_{S^2 \rho} = (\chi_{\rho})^2 - \chi^{\wedge^2 \rho}$. Therefore
\[
\chi^{S^2 \rho}(g) = \frac{1}{2}\left((\chi_{\rho}(g))^2 + \chi_{\rho}(g^2)\right).
\]

3. The calculation yields
\[
\chi^{\wedge^2 (\rho_4)} = (6, 0, 0, 0, 1, -2, 0) \quad \text{and} \quad \chi^{S^2 (\rho_4)} = (10, 4, 1, 0, 0, 2, 1).
\]

We have $(\chi^{\wedge^2 (\rho_4)}|\chi^{\wedge^2 (\rho_4)}) = \frac{1}{120}(36+24+60) = 1$, and thus $\wedge^2 (\rho_4)$ is irreducible. On the other hand,
\[
(\chi_{S^2 (\rho_4)}|\chi_{S^2 (\rho_4)}) = \frac{1}{120}(100 + 160 + 20 + 60 + 20) = 3.
\]

We cannot write $3 = \sum m_i^2$, where the $m_i$ are integers, unless three of them are equal to 1 and the others are zero. We have
\[
(\chi_{\rho_1}|\chi_{S^2 (\rho_4)}) = 1, \quad (\chi_{\rho_4}|\chi_{S^2 (\rho_4)}) = 1,
\]
and thus $S^2 (\rho_4) = \rho_1 \oplus \rho_4 \oplus \rho_5$, where dim$\rho_5 = 5$ and $\chi_{\rho_5} = (5, 1, -1, -1, 0, 1, 1)$; thus $(\chi_{\rho_5}|\chi_{\rho_5}) = 1$, and $\rho_5$ is therefore irreducible.

4. We denote by $\rho_6 = \wedge^2 (\rho_4)$ the six-dimensional irreducible representation of $\mathcal{S}_5$. We obtain the character table of $\mathcal{S}_5$:

<table>
<thead>
<tr>
<th></th>
<th>1</th>
<th>10</th>
<th>20</th>
<th>30</th>
<th>24</th>
<th>15</th>
<th>20</th>
</tr>
</thead>
<tbody>
<tr>
<td>$\rho_1$</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>1</td>
</tr>

</tbody>
</table>
We verify the orthogonality of the columns and of the rows, weighted by the number of elements of each class.

**Part II: Character table of \( \mathfrak{A}_5 \)**

5. Using the preceding table, we obtain the following characters of \( \mathfrak{A}_5 \):

\[
\begin{array}{cccccc}
\hline
 & e & \alpha & \beta & \gamma & \gamma^2 \\
\hline
\rho_1 & 1 & 1 & 1 & 1 & 1 \\
\rho_4 & 4 & 1 & 0 & -1 & -1 \\
\rho_5 & 5 & -1 & 1 & 0 & 0 \\
\rho_6 & 6 & 0 & -2 & 1 & 1 \\
\hline
\end{array}
\]

We see that

\[
(x_{\rho_1}|x_{\rho_1}) = 1, \quad (x_{\rho_4}|x_{\rho_4}) = 1, \quad (x_{\rho_5}|x_{\rho_5}) = 1, \quad (x_{\rho_6}|x_{\rho_6}) = 2.
\]

Thus the representations \( \rho_1, \rho_4, \rho_5 \) are irreducible and \( \wedge^2(\rho_4) = \rho_6 = \rho_3 \oplus \rho_3' \) with \( (\dim \rho_3)^2 + (\dim \rho_3')^2 + 1 + 16 + 25 = 60 \), and hence

\[
\dim \rho_3 = \dim \rho_3' = 3.
\]

6. Let \((3, A, B, C, D)\) and \((3, A', B', C', D')\) be the last two rows of the character table of \( \mathfrak{A}_5 \). Using the orthogonality of columns and rows, we obtain \( A = A' = 0, B = B' = -1, C + D = 1, C' + D' = 1, C'^2 - D'^2 = 0 \). Because \( D' = -C \) is impossible, we have \( D' = C \) and \( C' = D \), whence \( C'^2 - C - 1 = 0 \). We can choose \( C = \tau \), and then \( C' = \tau - 1, D = 1 - \tau, D' = \tau \). If we had chosen \( C = 1 - \tau \), we would only have inverted the last two rows of the character table.

7. Hence we obtain the character table of \( \mathfrak{A}_5 \):

\[
\begin{array}{cccccc}
\hline
 & e & \alpha & \beta & \gamma & \gamma^2 \\
\hline
\rho_1 & 1 & 1 & 1 & 1 & 1 \\
\rho_4 & 4 & 1 & 0 & -1 & -1 \\
\rho_5 & 5 & -1 & 1 & 0 & 0 \\
\rho_3 & 3 & 0 & -1 & \tau & 1 - \tau \\
\rho_3' & 3 & 0 & -1 & 1 - \tau & \tau \\
\hline
\end{array}
\]
Part III: Some representations of the icosahedron group

8. In the projection $\varphi : \text{SU}(2) \to \text{SO}(3)$, the element

$$g_\alpha = \exp(2\alpha \xi_3) = \begin{pmatrix} e^{i\alpha} & 0 \\ 0 & e^{-i\alpha} \end{pmatrix}$$

projects to the rotation through an angle $2\alpha$:

$$\text{Rot}(e_3, 2\alpha) = \exp(2\alpha \eta_3) = \begin{pmatrix} \cos 2\alpha & -\sin 2\alpha & 0 \\ \sin 2\alpha & \cos 2\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix}.$$ 

We know that $\chi_{D^j}(g_\alpha) = \sum_{m=-j}^{j} e^{2im\alpha}$, whence

$$\chi_{D^j}(\text{Rot}(e_3, \theta)) = \chi_{D^j}(g_\theta) = \sum_{m=-j}^{j} e^{im\theta}.$$ 

9. We calculate

$$\chi^j(\theta) = \sum_{m=-j}^{j} e^{im\theta} = \frac{\sin(j + \frac{1}{2})\theta}{\sin \frac{\theta}{2}},$$

for $\theta \neq 0$. We obtain $\chi^j(0) = 2j + 1$ and for $\theta = 2\pi/3$, $\pi$, $2\pi/5$, $4\pi/5$,

$$\chi^j\left(\frac{2\pi}{3}\right) = \begin{cases} 1 & \text{if } j \equiv 0 \pmod{3}, \\
0 & \text{if } j \equiv 1 \pmod{3}, \\
-1 & \text{if } j \equiv 2 \pmod{3}, \end{cases}$$

$$\chi^j(\pi) = \begin{cases} 1 & \text{if } j \equiv 0 \pmod{2}, \\
-1 & \text{if } j \equiv 1 \pmod{2}, \end{cases}$$

$$\chi^j\left(\frac{2\pi}{5}\right) = \begin{cases} 1 & \text{if } j \equiv 0 \pmod{5}, \\
2\cos \frac{\pi}{5} = \tau & \text{if } j \equiv 1 \pmod{5}, \\
0 & \text{if } j \equiv 2 \pmod{5}, \\
-2\cos \frac{\pi}{5} = -\tau & \text{if } j \equiv 3 \pmod{5}, \\
-1 & \text{if } j \equiv 4 \pmod{5}, \end{cases}$$

$$\chi^j\left(\frac{4\pi}{5}\right) = \begin{cases} 1 & \text{if } j \equiv 0 \pmod{5}, \\
1 - \tau & \text{if } j \equiv 1 \pmod{5}, \\
0 & \text{if } j \equiv 2 \pmod{5}, \\
\tau - 1 & \text{if } j \equiv 3 \pmod{5}, \\
-1 & \text{if } j \equiv 4 \pmod{5}. \end{cases}$$

It is thus clear that for every integer $\ell \in \mathbb{N}$ and each rotation $g \in I$ different from the identity,

$$\chi^{j+30\ell}(g) = \chi^j(g).$$
We can find the table of all characters $\chi^j$, for $0 \leq j \leq 29$. We write the first rows:

<table>
<thead>
<tr>
<th></th>

<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

10. We see immediately that $R^0 = \rho_1$ (the trivial representation), $R^1 = \rho_3$, and $R^2 = \rho_5$. Therefore $R^0$, $R^1$, and $R^2$ are irreducible. We denote by $\chi_1, \chi_3, \chi_3', \chi_4, \chi_5$ the characters of $\rho_1, \rho_3, \rho_3', \rho_4, \rho_5$. We have

$$(\chi_1|\chi^3) = 0, \quad (\chi_3|\chi^3) = 0, \quad (\chi_3'|\chi^3) = 1, \quad (\chi_4|\chi^3) = 1, \quad (\chi_5|\chi^3) = 0.$$  

Thus

$$R^3 = \rho_3' \oplus \rho_4.$$  

We set, for $m = 1, 3, 3', 4, 5$,

$$(\chi_m|\chi^j) = \frac{1}{60}((2j + 1)m + A^j_m),$$

where $m = m$ for $m = 1, 3, 4, 5$ and $m = 3$ for $m = 3'$. Then

$$(\chi_m|\chi^{30\ell+j}) = \frac{1}{60}((2j + 1 + 60\ell)m + A^j_m) = \ell m + (\chi_m|\chi^j).$$

Thus if $(\chi_m|\chi^j) = (a_1^j, a_3^j, a_3'^j, a_4^j, a_5^j)$, then

$$(\chi_m|\chi^{30\ell+j}) = a_1^j + \ell, \quad a_3^j + 3\ell, \quad a_3'^j + 3\ell, \quad a_4^j + 4\ell, \quad a_5^j + 5\ell.$$  

In particular,

$$(\chi_m|\chi^{30\ell+3}) = \ell, \quad 3\ell, \quad 3\ell + 1, \quad 4\ell + 1, \quad 5\ell,$$

whence

$$R^{30\ell+3} = \ell \rho_1 \oplus 3\ell \rho_3 \oplus (3\ell + 1)\rho_3' \oplus (4\ell + 1)\rho_4 \oplus 5\ell \rho_5.$$  

We verify that $2(30\ell + 3) + 1 = \ell + 9\ell + 9\ell + 3 + 16\ell + 4 + 25\ell$. 

11. In order to decompose $R^2 \otimes R^3$, we can use
\[ D^2 \otimes D^3 = D^1 \oplus D^2 \oplus D^3 \oplus D^4 \oplus D^5, \]
which implies the same relationship between the $D^j$ and thus between the $R^j$.

The decompositions of $R^4$ and of $R^5$ are
\[ R^4 = \rho_4 \oplus \rho_5, \quad R^5 = \rho_3 \oplus \rho'_3 \oplus \rho_5. \]

Hence
\[ R^2 \otimes R^3 = 2\rho_3 \oplus 2\rho'_3 \oplus 2\rho_4 \oplus 3\rho_5. \]

We verify that $5 \times 7 = 6 + 6 + 8 + 15$.

One can also write
\[ R^2 \otimes R^3 = \rho_5 \otimes (\rho'_3 \oplus \rho_4) = (\rho_5 \otimes \rho'_3) \oplus (\rho_5 \otimes \rho_4). \]

The character of $\rho_5 \otimes \rho'_3$ is $(15, 0, -1, 0, 0)$, and thus
\[ \rho_5 \otimes \rho'_3 = \rho_3 \oplus \rho'_3 \oplus \rho_4 \oplus \rho_5. \]

The character of $\rho_5 \otimes \rho_4$ is $(20, -1, 0, 0, 0)$, and hence
\[ \rho_5 \otimes \rho_4 = \rho_3 \oplus \rho'_3 \oplus 2\rho_4. \]

We recover
\[ R^2 \otimes R^3 = 2\rho_3 \oplus 2\rho'_3 \oplus 2\rho_4 \oplus 3\rho_5. \]

**Epilogue: Representations of** \( G = \varphi^{-1}(I) \subset SU2 \)

Each conjugacy class of \( G \) has a representative \( g_\alpha \), \( 0 \leq \alpha < 2\pi \).

<table>

</tr>
</tbody>
</table>

The class of \( e, \theta = 0 \), of order 1, yields \( \alpha = 0 \) (order 1) and \( \alpha = \pi \) (order 2).

The class with 15 elements, \( \theta = \pi \), of order 2, yields a class with 30 elements of order 4, \( \alpha = \pi/2 \).

The class with 20 elements, \( \theta = 2\pi/3 \), of order 3, yields a class with 20 elements of order 3, \( \alpha = 4\pi/3 \), and a class with 20 elements of order 6, \( \alpha = \pi/3 \).

Each class with 12 elements, \( \theta = 2\pi/5 \) (respectively, \( \theta = 4\pi/5 \)), of order 5, yields a class with 12 elements of order 5, \( \alpha = 6\pi/5 \) (respectively, \( \alpha = 2\pi/5 \)), and a class with 12 elements of order 10, \( \alpha = \pi/5 \) (respectively, \( \alpha = 7\pi/5 \)):
We can easily write the characters of the representations $\rho_1, \rho_3, \rho'_3, \rho_4, \rho_5$.

In addition, for $j = 1/2$, there are a representation $\rho_2$ obtained by restriction of $\mathcal{D}^{1/2}$ and a representation $\rho'_2$. The representations $\rho_1, \rho_3, \rho_4, \rho_5$ are the restrictions of $\mathcal{D}^0, \mathcal{D}^1, \mathcal{D}^{3/2}, \mathcal{D}^2$. Hence we obtain the character table of $G = \varphi^{-1}(\mathcal{I})$:

<table>
<thead>
<tr>
<th>order</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>6</th>
<th>3</th>
<th>10</th>
<th>10</th>
<th>5</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>cardinality</td>
<td>1</td>
<td>1</td>
<td>30</td>
<td>20</td>
<td>20</td>
<td>12</td>
<td>12</td>
<td>12</td>
<td>12</td>
</tr>
</tbody>
</table>

| $\mathcal{D}^0$ | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 | 1 |
| $\mathcal{D}^{1/2}$ | 2 | 2 | -2 | 0 | 1 | -1 | $\pi$ | $\pi$ | $\frac{2\pi}{3}$ |
| $\mathcal{D}^1$ | 3 | 3 | 3 | -1 | 0 | 0 | $\pi$ | $\pi$ | $\frac{2\pi}{3}$ |
| $\mathcal{D}^{3/2}$ | 4 | 4 | -4 | 0 | -1 | 1 | 1 | $\pi$ | $\pi$ |
| $\mathcal{D}^2$ | 5 | 5 | 5 | 1 | -1 | -1 | 0 | 0 | 0 |

$\mathcal{D}^0 \otimes \mathcal{D}^1 = \mathcal{D}^{1/2} \oplus 2 \mathcal{D}^{1/2}$, we obtain, for $k \geq 2$,

$$2 \otimes k = (k - 1) \oplus (k + 1).$$

Furthermore,

$$2 \otimes 2' = 4', \quad 2 \otimes 3' = 6' = 2' \otimes 3, \quad 2 \otimes 4' = 2' \oplus 6.$$

We can show that

$$3 \oplus 1 = 2 \otimes 2, \quad 4 \oplus 22 = 2 \otimes 3, \quad 5 \oplus 32 \otimes 2 = 2 \otimes 4 \otimes 1, \quad 6 \oplus 42 \otimes 3 = 2 \otimes 5 \otimes 32,$$

and similarly, $4', 3', 2'$ can be written in terms of linear combinations of tensor powers of $2$.

It is proved there that the multiplicities $a_{k,r}$ of the representations $r = 1, 2, \ldots, 2'$ in the restriction to $G$ of the representations $\mathcal{D}^{k/2}, k \in \mathbb{N}$, are the coefficients of the series expansion of a rational function, where only the numerator depends on $r$. 

Let $j$ be a nonnegative integer or half-integer. We denote by $V^j$ the complex vector space of homogeneous polynomials in two variables $(z_1, z_2)$ with complex coefficients, of degree $2j$.

1. To each matrix $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ belonging to $\text{SL}(2, \mathbb{C})$ and each polynomial $f \in V^j$, we associate the polynomial $\rho^j_V(g)f$ defined by

$$\rho^j_V(g)f(z_1, z_2) = f(az_1 + cz_2, bz_1 + dz_2).$$

Show that we have thus defined a representation $\rho^j_V$ of $\text{SL}(2, \mathbb{C})$ in $V^j$.

We denote by $P^j$ the complex vector space of polynomials with complex coefficients in one variable $x$ of degree $\leq 2j$.

2. Show that the map $\Phi$ of $V^j$ into $P^j$ defined by

$$(\Phi(f))(x) = f(x, 1),$$

for $f \in V^j$, is an isomorphism of vector spaces.

3. For $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}(2, \mathbb{C})$ and $\varphi \in P^j$, we define $\rho^j(g)(\varphi) \in P^j$ by

$$\rho^j(g)\varphi(x) = (bx + d)^{2j} \varphi \left( \frac{ax + c}{bx + d} \right).$$

Show that we have thus defined a representation $\rho^j$ of $\text{SL}(2, \mathbb{C})$ in $P^j$ equivalent to the representation $(V^j, \rho^j_V)$.

4. We denote by $r^j$ the differential of the representation $\rho^j$. Find the differential operator $r^j(X)$ for $X = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathfrak{sl}(2, \mathbb{C})$.

For $-j \leq m \leq j$ and $j - m$ integer, we set

$$\varphi^j_m(x) = \frac{x^{j-m}}{\sqrt{(j-m)!(j+m)!}}.$$

5. We consider the basis of $\mathfrak{sl}(2, \mathbb{C})$,

$$J_3 = \frac{1}{2} \begin{pmatrix} -1 & 0 \\ 0 & 1 \end{pmatrix}, \quad J_+ = \begin{pmatrix} 0 & 0 \\ -1 & 0 \end{pmatrix}, \quad J_- = \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix}.$$

Find the images under each of the operators $r^j(J_3)$, $r^j(J_+)$, $r^j(J_-)$ of the polynomials $\varphi^j_m$, for $-j \leq m \leq j$ and $j - m$ integer.

6. Show that the representation $\rho^j$ of $\text{SL}(2, \mathbb{C})$ on $P^j$ is irreducible.

7. Show that there is a unique scalar product on $P^j$ invariant under the restriction to $\text{SU}(2)$ of the representation $\rho^j$ of $\text{SL}(2, \mathbb{C})$ and such that the polynomials $\varphi^j_m$ form an orthonormal basis of $P^j$. Is the matrix of $\rho^j(g)$ in the basis $(\varphi^j_m)$ unitary for every $g \in \text{SL}(2, \mathbb{C})$?
We write \((\cdot | \cdot)\) for the scalar product defined above. The matrix coefficients \(\rho_{m,n}^j\) of the representation \(\rho^j\) in the basis \((\varphi_m^j)\) are defined by

\[
\rho_{m,n}^j(g) = (\varphi_m^j | \rho^j(g) \varphi_n^j),
\]
for \(g \in \text{SL}(2, \mathbb{C})\).

8. Let \(g = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{SL}(2, \mathbb{C})\). Use Taylor’s formula for the function \((ax + c)^j-n(bx + d)^j+n\), along with a change of variable, to show that if \(a \neq 0\) and \(b \neq 0\), then

\[
\rho_{m,n}^j(g) = C(j, m, n) \frac{b^{n-m}}{a^{n+m}} \frac{d^{j-m}}{dx^{j+m}} ((1-x)^{j-n}(1+x)^{j+n}) \bigg|_{x=ad+bc},
\]
where \(C(j, m, n)\) is a constant to be determined.

9. (a) Let \(\xi_1 = \begin{pmatrix} 0 \\ i \end{pmatrix}\). We set \(\rho^j(\theta) = \rho^j(\exp(\theta\xi_1))\), \(0 \leq \theta \leq \pi\). Find \(\rho^j(\pi)\).

(b) We assume that \(j\) and \(m\) are integers and that \(m \geq 0\). We recall that the Legendre function \(P_{j,m}^j(x)\) is defined, for \(-1 \leq x \leq 1\), by

\[
P_{j,m}(x) = \frac{(1)^{j+m}}{2^j j!} \frac{d^{j+m}}{dx^{j+m}} (1-x^2)^j.
\]

Show that \(\rho_{m,0}^j(\theta) = P_{m,0}^j(\cos \theta)\), where \(P_{m,0}^j\) is a function of one variable proportional to \(P_{j,m}(x)\), and find the coefficient of proportionality.

For \(-j \leq m \leq j\), what is the relation between the function \(\rho_{m,0}^j(\theta)e^{im\phi}\) and the spherical harmonic \(Y_{j,m}^j(\theta, \phi)\) \((0 \leq \theta \leq \pi, 0 \leq \phi < 2\pi)\)?

10. Prove the orthonormality property of the system of spherical harmonics from the orthogonality relations for the matrix coefficients of irreducible representations of \(\text{SU}(2)\).

Solutions

1. For every matrix \(g \in \text{SL}(2, \mathbb{C})\) and for every \(f \in V^j\), the polynomial \(\rho_{j,V}^j(g)f\) is homogenous of degree \(2j\), and its coefficients depend continuously on the coefficients of the matrix \(g\). The definition can be written \(\rho_{j,V}^j(g)f = f \circ \ i g;\) hence if \(g_1\) and \(g_2\) \(\in \text{SL}(2, \mathbb{C})\),

\[
\rho_{j,V}^j(g_1g_2)f = f \circ \ i g_2 \ i g_1 = \rho_{j,V}^j(g_1)(\rho_{j,V}^j(g_2)f).
\]

Thus \(\rho_{j,V}^j\) is a representation of \(\text{SL}(2, \mathbb{C})\) on \(V^j\).

2. It is clear that \(\Phi\) is linear. The vector spaces \(V^j\) and \(P^j\) have the same dimension, \(2j + 1\). Furthermore, \(\Phi\) is injective. In fact, if \(\Phi(f) = 0\), all the coefficients of the homogeneous polynomial \(f\) are zero, and hence it is zero. Thus \(\Phi\) is an isomorphism. The inverse \(\Psi\) of \(\Phi\) is given by

\[
(\Psi(\varphi))(z_1, z_2) = z_2^{2j} \varphi \left( \frac{z_1}{z_2} \right), \quad \varphi \in P^j.
\]
3. When we identify $V^j$ with $P^j$ by means of the isomorphism $\Phi$, the transformation $\rho^j_V(g)$ can be identified with the transformation $\rho^j(g)$. In fact, for $f \in V^j$,

$$
\rho^j(g)(\Phi(f))(x) = (bx + d)^{2j}(\Phi(f)) \left( \frac{ax + c}{bx + d} \right) = (bx + d)^{2j} f \left( \frac{ax + c}{bx + d}, 1 \right) = f(ax + c, bx + d) = (\rho^j_V(g)f)(x) = \Phi(\rho^j_V(g)f)(x).
$$

We deduce that $\rho^j$ is a representation of $\text{SL}(2, \mathbb{C})$ in $P^j$, equivalent to $\rho^j_V$. The isomorphism $\Phi$ intertwines the representations $\rho^j_V$ and $\rho^j$.

4. Let $X = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \in \mathfrak{sl}(2, \mathbb{C})$. Then $\exp(tX) = \begin{pmatrix} a(t) & b(t) \\ c(t) & d(t) \end{pmatrix}$ is a matrix of $\text{SL}(2, \mathbb{C})$ such that $a(0) = d(0) = 1$, $b(0) = c(0) = 0$, and $a'(0) = \alpha$, $b'(0) = \beta$, $c'(0) = \gamma$, $d'(0) = \delta$. One thus obtains, for $\varphi \in P^j$,

$$
(r^j(X)\varphi)(x) = \frac{d}{dt} \rho^j(\exp tX)\varphi)(x) \bigg|_{t=0} = \frac{d}{dt} (b(t)x + d(t))^{2j}\varphi \left( \frac{a(t)x + c(t)}{b(t)x + d(t)} \right) \bigg|_{t=0} = 2j(\beta x + \delta)\varphi(x) + (-\beta x^2 + (\alpha - \delta)x + \gamma) \frac{d\varphi}{dx}(x),
$$

that is,

$$
r^j(X) = 2j(\beta x + \delta) + (-\beta x^2 + (\alpha - \delta)x + \gamma) \frac{d}{dx}.
$$

5. In particular,

$$
r^j(J_3) = j - x \frac{d}{dx}, \quad r^j(J_+) = -\frac{d}{dx}, \quad r^j(J_-) = -2jx + x^2 \frac{d}{dx},
$$

and hence

$$
r^j(J_3)(\varphi^j_m) = m \varphi^j_m,
$$

$$
r^j(J_+)(\varphi^j_m) = -\sqrt{(j - m)(j + m + 1)} \varphi^j_{m+1},
$$

$$
r^j(J_-)(\varphi^j_m) = -\sqrt{(j + m)(j - m + 1)} \varphi^j_{m-1}.
$$

6. The preceding equations show that the representation $r^j$ of $\mathfrak{sl}(2, \mathbb{C})$ is equivalent to the representation $D^j$, the basis $(-1)^{j-m} \varphi^j_m$ corresponding to the standard basis $|j,m\rangle$. We know that this representation is irreducible. We deduce immediately that the representation $\rho^j$ of $\text{SL}(2, \mathbb{C})$ is irreducible.

7. There exists a unique scalar product on $P^j$ such that the basis $(\varphi^j_m)$ is orthonormal. Let us show that this scalar product is invariant under $\rho^j|_{\text{SU}(2)}$, that is, that the restriction of $\rho^j$ to $\text{SU}(2)$ is unitary for this scalar product. Because $\text{SU}(2)$ is connected, it suffices to show that the matrices in the basis $(\varphi^j_m)$ of the operators $r^j(\xi_k)$, $k = 1, 2, 3$, are anti-Hermitian, or equivalently, that the matrices of $r^j(J_+)$ and $r^j(J_-)$ are conjugate transposes of one another,
and that the matrix of \( r^j(J_3) \) is Hermitian. Because the operator \( r^j(J_3) \) is real and diagonal, it is Hermitian. We have

\[
(r^j(J_+)\varphi_m|\varphi_n^j) = -\sqrt{(j-m)(j+m+1)}\delta_{m+1,n}, \\
(\varphi_m^j|r^j(J_-)\varphi_n^j) = -\sqrt{(j+n)(j-n+1)}\delta_{m,n-1} \\
= -\sqrt{(j+m+1)(j-m)}\delta_{m+1,n},
\]

which shows that the matrices of \( r^j(J_+) \) and \( r^j(J_-) \) are real and are transposes of one another. The operators \( \rho^j(g) \) are thus unitary for \( g \in SU(2) \). But clearly this is not true for an arbitrary element of \( SL(2,\mathbb{C}) \): the operators \( r^j(X) \) are anti-Hermitian for \( X \in \mathfrak{su}(2) \) and Hermitian for \( X \in i\mathfrak{su}(2) \).

8. The coefficient of \( x^{j-m} \) in \((ax + c)^{j-n}(bx + d)^{j+n}\) is

\[
\frac{1}{(j-m)!} \frac{\partial^{j-m}}{\partial x^{j-m}}((ax + c)^{j-n}(bx + d)^{j+n})|_{x=0},
\]

and hence

\[
\rho^j_{m,n}(g) = \left( \frac{x^{j-m}}{\sqrt{(j-m)!(j+m)!}} \frac{\partial^{j-m}}{\partial y^{j-m}}((1-y)^{j-n}(1+y)^{j+n})|_{y=ad+bc} \right) \\
= \frac{\sqrt{(j+m)!}}{\sqrt{(j-n)!(j+n)!(j-m)!}} \frac{\partial^{j-m}}{\partial x^{j-m}}((ax + c)^{j-n}(bx + d)^{j+n})|_{x=0}.
\]

We set \( \frac{y+1}{2} = a(bx + d) \). Taking the equation \( ad - bc = 1 \) into account, we have \( \frac{y-1}{2} = b(ax + c) \). We assume \( a \neq 0 \) and \( b \neq 0 \). Because the variable \( y \) is a linear function of \( x \), we obtain

\[
\rho^j_{m,n}(g) = C(j, m, n) \frac{b^{n-m}}{a^{n+m}} \frac{\partial^{j-m}}{\partial y^{j-m}}((1-y)^{j-n}(1+y)^{j+n})|_{y=ad+bc},
\]

where

\[
C(j, m, n) = \frac{(-1)^{j-n}}{2^{j+m}} \frac{\sqrt{(j+m)!}}{\sqrt{(j-n)!(j+n)!(j-m)!}}.
\]

9. (a) We know that \( \exp(\theta \xi_1) = \left( \begin{array}{cc} \cos \theta & i \sin \theta \\ i \sin \theta & \cos \theta \end{array} \right) \). In particular, \( \exp(\pi \xi_1) = (0 \ i) \).

Now, \( (\rho^j(\pi)\varphi_m)(x) = \frac{1}{\sqrt{(j-m)!(j+m)!}} i^{2j} x^{j+m} = i^{2j}\varphi_m^j(x) \), and thus

\[
\rho^j(\pi)\varphi_m^j = i^{2j}\varphi_m^j, \quad \rho^j_{m,n}(\pi) = i^{2j}\delta_{m,-n}.
\]

From the equation \( \rho^j(\theta)\rho^j(\pi) = \rho^j(\pi)\rho^j(\theta) \), we deduce that

\[
\rho^j_{m,-n}(\theta) = \rho^j_{-m,n}(\theta).
\]

In particular, \( \rho^j_{m,0}(\theta) = \rho^j_{-m,0}(\theta) \).
(b) For $0 < \theta < \pi$, we calculate $\rho_{m,0}^j(\theta) = \rho_{-m,0}^j(\theta)$ by the general formula obtained above. We obtain

$$\rho_{m,0}^j(\theta) = \frac{(-1)^j}{2^j j!} \sqrt{\frac{(j-m)!}{(j+m)!}} i^m \sin^m \theta \frac{d^{j+m}}{dx^{j+m}} (1-x^2)^j|_{x=\cos \theta}.$$ 

When $0 \leq \theta \leq \pi$, the equation $\sin \theta = (1-\cos^2 \theta)^{\frac{1}{2}}$ is valid. Consequently, for $0 < \theta < \pi$, $P_{m}^j(\theta) = P_{m}^j(\cos \theta)$, where the function $P_m^j$ is defined for $-1 \leq x \leq 1$ by

$$P_m^j(x) = \frac{(-1)^j}{2^j j!} \sqrt{\frac{(j-m)!}{(j+m)!}} i^m (1-x^2)^{\frac{m}{2}} \frac{d^{j+m}}{dx^{j+m}} (1-x^2)^j.$$ 

We verify that for $j$ and $m$ integers, $m \geq 0$, $P_m^j(1) = \delta_{m,0}$ and $P_m^j(-1) = (-1)^j \delta_{m,0}$, which extends the result to the case $\theta = 0$ and $\theta = \pi$. If we use $P_{j,m}$ to denote the Legendre function, we obtain an equation valid for $0 \leq \theta \leq \pi$,

$$\rho_{m,0}^j(\theta) = \sqrt{\frac{(j-m)!}{(j+m)!}} i^m P_{j,m}(\cos \theta).$$

We know that for $0 \leq m \leq j$, the spherical harmonics are the functions

$$Y_m^j(\theta, \Phi) = \sqrt{\frac{2j+1}{4\pi}} \sqrt{\frac{(j-m)!}{(j+m)!}} P_{j,m}(\cos \theta) e^{im\Phi}.$$ 

We deduce that in this case,

$$Y_m^j(\theta, \phi) = \sqrt{\frac{2j+1}{4\pi}} i^m \rho_{m,0}^j(\theta) e^{im\phi}.$$ 

This equation is valid for $-j \leq m < 0$ as well. In fact, by definition, $Y_m^j = (-1)^m Y_{-m}^{-j}$; therefore, $Y_m^j = (-1)^m \sqrt{\frac{2j+1}{4\pi}} i^m \rho_{-m,0}^j(\theta) e^{im\phi}$. Since $\rho_{-m,0}^j(\theta) = \rho_{m,0}^j(\theta)$ and $\rho_{m,0}^j(\theta) = (-1)^m \rho_{m,0}^j(\theta)$, the result follows.

10. We know that a dense open set of $SU(2)$ is parametrized by the Euler angles. For a matrix $g = \begin{pmatrix} a & b \\ -b & a \end{pmatrix} \in SU(2)$ such that $Im(a) \neq 0$, $Re(b) \neq 0$, there are unique parameters $\phi \in [0, 2\pi]$, $\theta \in [0, \pi]$, $\psi \in [-2\pi, 2\pi]$ such that

$$g = g(\phi, \theta, \psi) = \begin{pmatrix} \cos \frac{\theta}{2} e^{i \frac{\phi+\psi}{2}} & i \sin \frac{\theta}{2} e^{i \frac{\phi-\psi}{2}} \\ i \sin \frac{\theta}{2} e^{-i \frac{\phi-\psi}{2}} & \cos \frac{\theta}{2} e^{-i \frac{\phi+\psi}{2}} \end{pmatrix} = \exp(\phi \xi_3) \exp(\theta \xi_1) \exp(\psi \xi_3).$$

In this parametrization, the Haar integral on $SU(2)$ can be written

$$I(f) = \frac{1}{16\pi^2} \int_{0}^{2\pi} \int_{0}^{\pi} \int_{-2\pi}^{2\pi} f(g(\phi, \theta, \psi)) \sin \theta \, d\phi \, d\theta \, d\psi.$$
Now consider the matrix coefficients of the representation $\rho^j$ of SU(2).

Because $g(\phi,0,0) = \exp(\phi \xi_3) = \begin{pmatrix} e^{i\phi/2} & 0 \\ 0 & e^{-i\phi/2} \end{pmatrix}$, for each function $\varphi \in P^j$, we obtain $(\rho^j(g(\phi,0,0))\varphi)(x) = e^{-ij\phi}\varphi(e^{i\phi}x)$, whence

$$\rho^j(g(\phi,0,0))x^j = e^{-im\phi}x^j.$$

The matrix of $\rho^j(g(\phi,0,0))$ in the basis $\varphi^j_m$ is thus diagonal, with elements $e^{-im\phi}$, $-j \leq m \leq j$. Similarly, the matrix of $\rho^j(g(0,0,\psi))$ is diagonal, with elements $e^{-im\psi}$.

We have set $\rho^j(\theta) = \rho^j(\exp(\theta \xi_1))$, i.e., $\rho^j(\theta) = \rho^j(g(0,\theta,0))$. By writing

$$\rho^j_{m,n}(g(\phi,\theta,\psi)) = \sum_{p,q}\rho^j_{m,p}(g(\phi,0,0))\rho^j_{p,q}(\theta)\rho^j_{n,q}(g(0,0,\psi)),$$

we obtain

$$\rho^j_{m,n}(g(\phi,\theta,\psi)) = e^{-i(m\phi+n\psi)}\rho^j_{m,n}(\theta).$$

In particular,

$$\rho^j_{m,0}(g(\phi,\theta,\psi)) = e^{-im\phi}\rho^j_{m,0}(\theta).$$

The orthogonality relations for the matrix coefficients of unitary irreducible representations $\rho^j$ of SU(2) imply

$$\frac{1}{16\pi^2} \int_0^{2\pi} \int_0^\pi \int_{-2\pi}^{2\pi} \rho^j_{m,0}(g(\phi,\theta,\psi))\rho^j_{m',0}(g(\phi,\theta,\psi)) \sin \theta \, d\phi \, d\theta \, d\psi = \frac{1}{2j+1} \delta_{m,m'}\delta_{j,j'},$$

whence, because $\rho^j_{m,0}$ does not depend on $\psi$,

$$\frac{2j+1}{4\pi} \int_0^{2\pi} \int_0^\pi \rho^j_{m,0}(g(\phi,\theta,0))\rho^j_{m',0}(g(\phi,\theta,0)) \sin \theta \, d\phi \, d\theta = \delta_{m,m'}\delta_{j,j'}.$$

The elements corresponding to $\psi = 0$ can be identified with the points of the sphere $S^2$: to $\exp(\phi \xi_3)\exp(\theta \xi_1)$ corresponds the point $\exp(\phi \eta_3)\exp(\theta \eta_1)e_3$, with spherical coordinates $(\theta, \phi - \frac{\pi}{2})$.

Now, for $j \in \mathbb{N}$, $-j \leq m \leq j$,

$$Y^j_m(\theta, \phi) = \sqrt{\frac{2j+1}{4\pi}} i^m e^{im\phi} \rho^j_{m,0}(\theta).$$

Furthermore, we know that $\rho^j_{m,0}(\theta)$ is either real or pure imaginary. This equation means that up to a coefficient, the spherical harmonic $Y^j_m(\theta, \phi)$ is the conjugate of the matrix coefficient $\rho^j_{m,0}(g(\phi, \theta, 0))$. Taking into account the
value of the modulus of this coefficient, the orthogonality relation above can be written

\[ \int_0^\pi \int_0^{2\pi} Y_{jm}(\theta, \phi) Y_{j'm'}(\theta, \phi) \sin \theta \, d\theta \, d\phi = \delta_{m,m'} \delta_{jj'}, \]

which proves that the spherical harmonics \((Y_{jm}^j), j \in \mathbb{N}, -j \leq m \leq j,\) form an orthonormal set in \(L^2(S^2)\) equipped with the unnormalized scalar product.

From the properties of the matrix coefficients of the irreducible representations of the group SU(2), one can prove the orthogonality properties, the addition theorems, and many other properties of the Legendre polynomials, the Legendre functions, and the spherical harmonics.
Hermann Weyl (1885–1955) wrote his doctoral dissertation in 1908 in Göttingen under the direction of David Hilbert, taught in Zurich from 1913 to 1930, succeeded Hilbert at Göttingen, and left Germany in 1933 for the United States, where he accepted a position at the newly formed Institute for Advanced Study in Princeton. His most important contributions to group theory date from the years 1920–1940.
